BOUNDARY HARNACK INEQUALITY FOR MARKOV PROCESSES WITH JUMPS

KRZYSZTOF BOGDAN, TAKASHI KUMAGAI, AND MATEUSZ KWAŚNICKI

ABSTRACT. We prove a boundary Harnack inequality for jump-type Markov processes on metric measure state spaces, under comparability estimates of the jump kernel and Urysohn-type property of the domain of the generator of the process. The result holds for positive harmonic functions in arbitrary open sets. It applies, e.g., to many subordinate Brownian motions, Lévy processes with and without continuous part, stable-like and censored stable processes, jump processes on fractals, and rather general Schrödinger, drift and jump perturbations of such processes.

1. INTRODUCTION

The boundary Harnack inequality (BHI) is a statement about nonnegative functions which are harmonic on an open set and vanish outside the set near a part of its boundary. BHI asserts that the functions have a common boundary decay rate. The property requires proper assumptions on the set and the underlying Markov process, ones which secure relatively good communication from near the boundary to the center of the set. By this we mean that the process starting near the boundary visits the center of the set at least as likely as creep far along the boundary before leaving the set.

BHI for harmonic functions of the Laplacian Δ in Lipschitz domains was proved in 1977–78 by B. Dahlberg, A. Ancona and J.-M. Wu ([4, 37, 80]), after a pioneering attempt of J. Kemper ([55, 56]). In 1989 R. Bass and K. Burdzy proposed an alternative probabilistic proof based on elementary properties of the Brownian motion ([13]). The resulting 'box method' was then applied to more general domains, including Hölder domains of order $r > 1/2$, and to more general second order elliptic operators ([14, 15]). BHI trivially fails for disconnected sets, and counterexamples for Hölder domains with $r<1/2$ are given in [15]. In 2001–09, H. Aikawa studied BHI for classical harmonic functions in connection to the Carleson estimate and under exterior capacity conditions ([1, 2, 3]).

Moving on to nonlocal operators and jump-type Markov processes, in 1997 K. Bogdan proved BHI for the fractional Laplacian $\Delta^{\alpha/2}$ (and the isotropic α-stable Lévy process) for $0 < \alpha < 2$ and Lipschitz sets ([19]). In 1999 R. Song and J.-M. Wu extended the results to the so-called fat sets ([73]), and in 2007 K. Bogdan, T. Kulczycki and M. Kwaśnicki proved BHI for $\Delta^{\alpha/2}$ in arbitrary, in particular disconnected, open sets ([26]). In 2008 P. Kim, R. Song and Z. Vondraček proved BHI for subordinate Brownian motions in fat sets ([61]) and in 2011 extended it to a general class of isotropic Lévy processes and arbitrary domains ([63]). Quite recently, BHI for $\Delta+\Delta^{\alpha/2}$ was established by Z.-Q. Chen, P. Kim, R. Song and Z. Vondraček [32]. We also like to mention BHI for censored [43] by Q. Guan and fractal jump processes [53, 75] by K. Kaleta and M. Kwaśnicki.

Generally speaking, BHI is more a topological issue for diffusion processes, and more a measure-theoretic issue for jump-type Markov processes, which may transport from near the boundary to the center of the set by direct jumps. However, direct jumps fully explain the asymptotics of harmonic functions only at points where the set is rather thin, and for other points a more complex interplay occurs between large jumps and gradual 'excursions' away from the boundary, see [19, 26] (the corresponding classification of the boundary points seems to be of considerable importance).

We recall that BHI in particular applies to and may yield an approximate factorization of the Green function. This line of research was completed for Lipschitz domains in 2000 by K. Bogdan ([20]) for Δ and in 2002 by T. Jakubowski ([50]) for $\Delta^{\alpha/2}$. It is now a well-established technique ([46]) and extensions were proved, e.g., for subordinate Brownian motions by P. Kim, R. Song and Z. Vondraček ([64]). We should note that so far the technique is typically restricted to Lipschitz or fat sets. Furthermore, for smooth sets, e.g. $C^{1,1}$ sets, the approximate factorization is usually more explicit. This is so because for smooth sets the decay rate in BHI can often be explicitly expressed in terms of the distance to the boundary of the set. The first complete results in this direction were given for Δ in 1986 by Z. Zhao ([81]) and for $\Delta^{\alpha/2}$ in 1997 by T. Kulczycki ([65]) and in 1998 by Z.-Q. Chen and R. Song ([35]). The estimates are now extended to subordinate Brownian motions, and the renewal function of the subordinator is used in the corresponding formulations ([64]). Accordingly, the Green function of smooth sets enjoys approximate factorization for rather general isotropic Lévy processes ([29, 64]). We expect further progress in this direction with applications to perturbation theory via the so-called 3G theorems, and to nonlinear partial differential equations ([25, 46, 68]). We should also mention estimates and approximate factorization of the Dirichlet heat kernels, which are intensively studied at present. The estimates depend on BHI ([24]), and reflect the fundamental decay rate in BHI ([31, 45]).

BHI tends to self-improve and may lead to the existence of the boundary limits of ratios of nonnegative harmonic functions, thanks to oscillation reduction ([13, 19, 26, 52]). The oscillation reduction technique is rather straightforward for local operators. It is more challenging for non-local operators, as it involves subtraction of harmonic functions, which destroys global nonnegativity. The technique requires a certain scale invariance, or uniformity of BHI, and works, e.g., for Δ in Lipschitz domains ([13]) and for $\Delta^{\alpha/2}$ in arbitrary domains ([26]). We should remark that Hölder continuity of harmonic functions is a similar phenomenon, related to the usual Harnack inequality, and that BHI extends the usual Harnack inequality if, e.g., constant functions are harmonic. Hölder continuity of harmonic functions is crucial in the theory of partial differential equations [6, 16], and the existence of limits of ratios of nonnegative harmonic functions leads to the construction of the Martin kernel and to representation of nonnegative harmonic functions ([5, 26]).

The above summary indicate further directions of research resulting from our development. The main goal of this article is to study the following boundary Harnack inequality. In Section 2 we specify notation and assumptions which validate the estimate.

(BHI) Let $x_0 \in \mathfrak{X}$, $0 < r < R < R_0$, and let $D \subseteq B(x_0, R)$ be open. Suppose that nonnegative functions f, g on $\mathfrak{X}$ are regular harmonic in D with respect to the process X_t, and vanish in $B(x_0, R) \setminus D$. There is $c_{(1.1)} = c_{(1.1)}(x_0, r, R)$ such that

$$f(x)g(y) \le c_{(1.1)}\, f(y)g(x)\,, \qquad x, y \in B(x_0, r). \tag{1.1}$$

Here X_t is a Hunt process, having a metric measure space $\mathfrak{X}$ as the state space, and $R_0 \in (0, \infty]$ is a localization radius (discussed in Section 2). Also, a nonnegative function f is said to be regular harmonic in D with respect to X_t if

$$f(x) = \mathbf{E}_x f(X_{\tau_D}), \qquad x \in D, \tag{1.2}$$

where τ_D is the time of the first exit of X_t from D. To facilitate cross-referencing, in (1.1) and later on we let $c_{(i)}$ denote the constant in the displayed formula (i). By c or c_i we denote secondary (temporary) constants in a lemma or a section, and $c = c(a, \dots, z)$, or simply $c(a, \dots, z)$, means a constant c that may be so chosen to depend only on $a, \dots, z$. Throughout the article, all constants are positive.

The present work started with an attempt to obtain *bounded* kernels which reproduce harmonic functions. We were motivated by the so-called regularization of the Poisson kernel for $\Delta^{\alpha/2}$ ([22], [26, Lemma 6]), which is crucial for the Carleson estimate and BHI for $\Delta^{\alpha/2}$. In the present paper we construct kernels obtained by gradually stopping the Markov process with a specific multiplicative functional before the process approaches the boundary. The construction is the main technical ingredient of our work, and is presented in Section 4. The argument is intrinsically probabilistic and relies on delicate analysis on the path space. At the beginning of Section 4 the reader will also find a short informal presentation of the construction. Section 2 gives assumptions and auxiliary results. The boundary Harnack inequality (Theorem 3.5), and the so-called local supremum estimate (Theorem 3.4) are presented in Section 3, but the proof of Theorem 3.4 is deferred to Section 4. In Section 5 we verify in various settings the scale-invariance of BHI, discuss the relevance of our main assumptions from Section 2, and present many applications, including subordinate Brownian motions, Lévy processes with or without continuous part, stable-like and censored processes, Schrödinger, gradient and jump perturbations, processes on fractals and more.

2. Assumptions and Preliminaries

Let $(\mathfrak{X}, d, m)$ be a metric measure space such that all bounded closed sets are compact and m has full support. Let $B(x, r) = \{y \in \mathfrak{X} : d(x, y) < r\}$, where $x \in \mathfrak{X}$ and $r > 0$. All sets, functions and measures considered in this paper are Borel. Let $R_0 \in (0, \infty]$ (the localization radius) be such that $\mathfrak{X} \setminus B(x, 2r) \neq \varnothing$ for all $x \in \mathfrak{X}$ and all $r < R_0$. Let $\mathfrak{X} \cup \{\partial\}$ be the one-point compactification of $\mathfrak{X}$ (if $\mathfrak{X}$ is compact, then we add ∂ as an isolated point). Without much mention we extend functions f on $\mathfrak{X}$ to $\mathfrak{X} \cup \{\partial\}$ by letting $f(\partial) = 0$. In particular, we write $f \in C_0(\mathfrak{X})$ if f is a continuous real-valued function on $\mathfrak{X} \cup \{\partial\}$ and $f(\partial) = 0$. If furthermore f has compact support in $\mathfrak{X}$, then we write $f \in C_c(\mathfrak{X})$. For a kernel $k(x, dy)$ on $\mathfrak{X}$ ([38]) we let $kf(x) = \int f(y) k(x, dy)$, provided the integral makes sense, i.e., f is (measurable and) either nonnegative or absolutely integrable. Similarly, for a kernel density function $k(x, y) \geq 0$, we let $k(x, E) = \int_E k(x, y) m(dy)$ and $k(E, y) = \int_E k(x, y) m(dx)$ for $E \subseteq \mathfrak{X}$.

Let $(X_t, \zeta, \mathcal{M}_t, \mathbf{P}_x)$ be a Hunt process with state space $\mathfrak{X}$ (see, e.g., [18, I.9] or [39, 3.23]). Here X_t are the random variables, $\mathcal{M}_t$ is the usual right-continuous filtration, $\mathbf{P}_x$ is the distribution of the process starting from $x \in \mathfrak{X}$, and $\mathbf{E}_x$ is the corresponding expectation. The random variable $\zeta \in (0, \infty]$ is the lifetime of X_t, so that $X_t = \partial$ for $t \geq \zeta$. This should be kept in mind when interpreting (1.2) above, (2.1) below, etc. The transition operators of X_t are defined by

$$T_t f(x) = \mathbf{E}_x f(X_t), \qquad t \geq 0,\ x \in \mathfrak{X}, \tag{2.1}$$

whenever the expectation makes sense. We assume that the semigroup T_t is Feller and strong Feller, i.e., for $t > 0$, T_t maps bounded functions into continuous ones and $C_0(\mathfrak{X})$ into $C_0(\mathfrak{X})$. The Feller generator $\mathcal{A}$ of X_t is defined on the set $\mathcal{D}(\mathcal{A})$ of all those $f \in C_0(\mathfrak{X})$ for which the limit

$$\mathcal{A} f(x) = \lim_{t \searrow 0} \frac{T_t f(x) - f(x)}{t}$$

exists uniformly in $x \in \mathfrak{X}$. The α-potential operator,

$$\mathcal{U}_\alpha f(x) = \mathbf{E}_x \int_0^\infty f(X_t) e^{-\alpha t} dt = \int_0^\infty e^{-\alpha t} T_t f(x) dt, \qquad \alpha \geq 0,\ x \in \mathfrak{X},$$

is defined whenever the expectation makes sense. We let $\mathcal{U} = \mathcal{U}_0$, the potential operator. The kernels of T_t, $\mathcal{U}_\alpha$ and $\mathcal{U}$ are denoted by $T_t(x, dy)$, $\mathcal{U}_\alpha(x, dy)$ and $\mathcal{U}(x, dy)$, respectively.

Recall that a function $f \geq 0$ is called α-excessive (with respect to T_t) if for all $x \in \mathfrak{X}$, $e^{-\alpha t} T_t f(x) \leq f(x)$ for $t > 0$, and $e^{-\alpha t} T_t f(x) \to f(x)$ as $t \to 0^+$. When $\alpha = 0$, we simply say that f is excessive.

We enforce a number of conditions, namely Assumptions A, B, C and D below. We start with a duality assumption, which builds on our discussion of X_t.

Assumption A. There are Hunt processes X_t and $\hat{X}_t$ which are dual with respect to the measure m (see [18, VI.1] or [36, 13.1]). The transition semigroups of X_t and $\hat{X}_t$ are both Feller and strong Feller. Every semi-polar set of X_t is polar.

In what follows, objects pertaining to $\hat{X}_t$ are distinguished in notation from those for X_t by adding a hat over the corresponding symbol. For example, $\hat{T}_t$ and $\hat{\mathcal{U}}_\alpha$ denote the transition and α-potential operators of $\hat{X}_t$. The first sentence of Assumption A means that for all $\alpha > 0$, there are functions $\mathcal{U}_\alpha(x, y) = \hat{\mathcal{U}}_\alpha(y, x)$ such that

$$\mathcal{U}_\alpha f(x) = \int_{\mathfrak{X}} \mathcal{U}_\alpha(x, y) f(y) m(dy), \qquad \hat{\mathcal{U}}_\alpha f(x) = \int_{\mathfrak{X}} \hat{\mathcal{U}}_\alpha(x, y) f(y) m(dy)$$

for all $f \geq 0$ and $x \in \mathfrak{X}$, and such that $x \mapsto \mathcal{U}_\alpha(x, y)$ is α-excessive with respect to T_t, and $y \mapsto \mathcal{U}_\alpha(x, y)$ is α-excessive with respect to $\hat{T}_t$ (that is, α-co-excessive). The α-potential kernel $\mathcal{U}_\alpha(x, y)$ is unique (see [36, Theorem 13.2] or remarks after [18, Proposition VI.1.3]).

The condition in Assumption A that semi-polar sets are polar is also known as *Hunt's hypothesis* (H). Most notably, it implies that the process X_t never hits irregular points, see, e.g., [18, I.11 and II.3] or [36, Chapter 3]. The α-potential kernel is non-increasing in $\alpha > 0$, and hence the potential kernel $\mathcal{U}(x, y) = \lim_{t \to 0^+} \mathcal{U}_\alpha(x, y) \in [0, \infty]$ is well-defined.

We consider an open set $D \subset \mathfrak{X}$ and the time of the first exit from D for X_t and $\hat{X}_t$,

$$\tau_D = \inf\{t \geq 0 : X_t \notin D\} \qquad \text{and} \qquad \hat{\tau}_D = \inf\{t \geq 0 : \hat{X}_t \notin D\}.$$

We define the processes killed at τ_D,

$$X_t^D = \begin{cases} X_t, & \text{if } t < \tau_D, \\ \partial, & \text{if } t \geq \tau_D, \end{cases} \qquad \text{and} \qquad \hat{X}_t^D = \begin{cases} \hat{X}_t, & \text{if } t < \hat{\tau}_D, \\ \partial, & \text{if } t \geq \hat{\tau}_D. \end{cases}$$

We let $T_t^D(x, dy)$ and $\hat{T}_t^D(x, dy)$ be their transition kernels. By [36, Remark 13.26], X_t^D and $\hat{X}_t^D$ are dual processes with state space D. Indeed, for each $x \in D$, $\mathbf{P}_x$-a.s. the process X_t only hits regular points of $\mathfrak{X} \setminus D$ when it exits D. In the nomenclature of [36, 13.6], this means that the left-entrance time and the hitting time of $\mathfrak{X} \setminus D$ are equal $\mathbf{P}^x$-a.s. for every $x \in D$. In particular, the potential kernel $G_D(x, y)$ of X_t^D exists and is unique, although in general it may be infinite ([18, pp. 256–257]). $G_D(x,y)$ is called the Green function for X_t on D, and it defines the Green operator G_D,

$$G_D f(x) = \int_{\mathfrak{X}} f(y) G_D(x,y) m(dy) = \mathbf{E}_x \int_0^{\tau_D} f(X_t) dt, \qquad x \in \mathfrak{X}, f \geq 0.$$

Note that $\mathcal{U}(x,y) = G_{\mathfrak{X}}(x,y)$. When X_t is symmetric (self-dual) with respect to m, then Assumption A is equivalent to the existence of the α-potential kernel $\mathcal{U}_\alpha(x,y)$ for X_t, since then Hunt's hypothesis (H) is automatically satisfied, see [36].

The following regularity hypothesis plays a crucial role in our paper, providing enough 'smooth' functions on $\mathfrak{X}$ to approximate indicator functions of compact sets.

Assumption B. There is a linear subspace $\mathcal{D}$ of $\mathcal{D}(\mathcal{A}) \cap \mathcal{D}(\hat{\mathcal{A}})$ satisfying the following condition. If K is compact, D is open, and $K \subseteq D \subseteq \mathfrak{X}$, then there is $f \in \mathcal{D}$ such that $f(x) = 1$ for $x \in K$, $f(x) = 0$ for $x \in \mathfrak{X} \setminus D$, $0 \leq f(x) \leq 1$ for $x \in \mathfrak{X}$, and the boundary of the set $\{x : f(x) > 0\}$ has measure m zero. We let

$$\varrho(K,D) = \inf_f \sup_{x \in \mathfrak{X}} \max(\mathcal{A}f(x), \hat{\mathcal{A}}f(x)), \tag{2.2}$$

where the infimum is taken over all such functions f.

Thus, nonnegative functions in $\mathcal{D}(\mathcal{A}) \cap \mathcal{D}(\hat{\mathcal{A}})$ separate the compact set K from the closed set $\mathfrak{X} \setminus D$: there is a Urysohn (bump) function for K and $\mathfrak{X} \setminus D$ in the domains.

Note that constant functions are not in $\mathcal{D}(\mathcal{A})$ nor $\mathcal{D}(\hat{\mathcal{A}})$ unless $\mathfrak{X}$ is compact. In the Euclidean case $\mathfrak{X} = \mathbf{R}^d$, $\mathcal{D}$ can often be taken as the class $C_c^\infty(\mathbf{R}^d)$ of compactly supported smooth functions. The existence of $\mathcal{D}$ is problematic if $\mathfrak{X}$ is more general. However, for the Sierpiński triangle and some other self-similar (p.c.f.) fractals, $\mathcal{D}$ can be constructed by using the concept of splines on fractals ([53, 76]). Also, a class of smooth indicator functions was recently constructed in [69] for heat kernels satisfying upper sub-Gaussian estimates on $\mathfrak{X}$. Further discussion is given in Section 5 and Appendix A. Here we note that Assumption B implies that the jumps of X_t are subject to the following identity, which we call the Lévy system formula for X_t,

$$\mathbf{E}_x \sum_{s \in [0,t]} f(s, X_{s-}, X_s) = \mathbf{E}_x \int_0^t \int_{\mathfrak{X}} f(s, X_{s-}, z) \nu(X_{s-}, dz) ds. \tag{2.3}$$

Here $f : [0,\infty) \times \mathfrak{X} \times \mathfrak{X} \to [0,\infty]$, $f(x,x) = 0$ for all $x \in \mathfrak{X}$, and ν is a kernel on $\mathfrak{X}$ (satisfying $\nu(x, \{x\}) = 0$ for all $x \in \mathfrak{X}$), called the Lévy kernel of X_t, see [17, 72, 78]. For more general Markov processes, ds in (2.3) is superseded by the differential of a perfect, continuous additive functional, and (2.3) defines $\nu(x, \cdot)$ only up to a set of zero potential, that is, for m-almost every $x \in \mathfrak{X}$. By inspecting the construction in [17, 72], and using Assumption B, one proves in a similar way as in [12, Section 5] that the Lévy kernel ν satisfies

$$\nu f(x) = \lim_{t \searrow 0} \frac{T_t f(x)}{t}, \qquad f \in C_c(\mathfrak{X}),\ x \in \mathfrak{X} \setminus \operatorname{supp} f. \tag{2.4}$$

This formula, as opposed to (2.3), defines $\nu(x,dy)$ for all $x \in \mathfrak{X}$. With only one exception, to be discussed momentarily, we use (2.4) and not (2.3), hence we take (2.4) as the definition of ν. It is easy to see that (2.4) indeed defines $\nu(x,dy)$: if $f \in \mathcal{D}(\mathcal{A})$ and $x \in \mathfrak{X} \setminus \operatorname{supp} f$, then $\nu f(x) = \mathcal{A}f(x)$. By Assumption B, the mapping $f \mapsto \nu f(x)$ is a densely defined, nonnegative linear functional on $C_c(\mathfrak{X} \setminus \{x\})$, hence it corresponds to a nonnegative Radon measure $\nu(x,dy)$ on $\mathfrak{X} \setminus \{x\}$. As usual, we let $\nu(x, \{x\}) = 0$. The

Lévy kernel $\hat{\nu}(y, dx)$ for $\hat{X}_t$ is defined in a similar manner. By duality, $\nu(x, dy)m(dx) = \hat{\nu}(y, dx)m(dy)$.

As an application of (2.3) we consider the martingale

$$t \mapsto \sum_{s\in[0,t]} f(s, X_{s-}, X_s) - \int_0^t \int_{\mathfrak{X}} f(s, X_{s-}, z)\nu(X_{s-}, dz)ds,$$

where $f(s, y, z) = \mathbf{1}_A(s)\mathbf{1}_E(y)\mathbf{1}_F(z)$. We stop the martingale at τ_D and we see that

$$\mathbf{P}_x(\tau_D \in dt, X_{\tau_D-} \in dy, X_{\tau_D} \in dz) = dt\, T_t^D(x, dy)\nu(y, dz), \tag{2.5}$$

on $(0, \infty) \times D \times (\mathfrak{X} \setminus D)$. A similar result was first proved in [49]. For this reason we refer to (2.5) as the Ikeda-Watanabe formula (see also (2.12) and (2.6) below). Integrating (2.5) against dt and dy we obtain

$$\mathbf{P}_x(X_{\tau_D-} \neq X_{\tau_D}, X_{\tau_D} \in E) = \int_D G_D(x, dy)\nu(y, E), \qquad x \in D,\, E \subset \mathfrak{X} \setminus D. \tag{2.6}$$

For $x_0 \in \mathfrak{X}$ and $0 < r < R$, we consider the open and closed balls $B(x_0, r) = \{x \in \mathfrak{X} : d(x_0, x) < r\}$ and $\overline{B}(x_0, r) = \{x \in \mathfrak{X} : d(x_0, x) \leq r\}$, and the annular regions $A(x_0, r, R) = \{x \in \mathfrak{X} : r < d(x_0, x) < R\}$ and $\overline{A}(x_0, r, R) = \{x \in \mathfrak{X} : r \leq d(x_0, x) \leq R\}$. Note that $\overline{B(x_0, r)}$, the closure of $B(x_0, r)$, may be a proper subset of $\overline{B}(x_0, r)$.

Recall that R_0 denotes the localization radius of $\mathfrak{X}$. The following assumption is our main condition for the boundary Harnack inequality. It asserts a relative constancy of the density of the Lévy kernel. This is a natural condition, as seen in Example 5.14.

Assumption C. The Lévy kernels of the processes X_t and $\hat{X}_t$ have the form $\nu(x, y)m(dy)$ and $\hat{\nu}(x, y)m(dy)$ respectively, where $\nu(x, y) = \hat{\nu}(y, x) > 0$ for all $x, y \in \mathfrak{X}$, $x \neq y$. For every $x_0 \in \mathfrak{X}$, $0 < r < R < R_0$, $x \in B(x_0, r)$ and $y \in \mathfrak{X} \setminus B(x_0, R)$,

$$c_{(2.7)}^{-1}\nu(x_0, y) \leq \nu(x, y) \leq c_{(2.7)}\nu(x_0, y), \quad c_{(2.7)}^{-1}\hat{\nu}(x_0, y) \leq \hat{\nu}(x, y) \leq c_{(2.7)}\hat{\nu}(x_0, y), \tag{2.7}$$

with $c_{(2.7)} = c_{(2.7)}(x_0, r, R)$.

It follows directly from Assumption C that for $x_0 \in \mathfrak{X}$ and $0 < r < R$,

$$c_{(2.8)}(x_0, r, R) = \inf_{y\in\overline{A}(x_0,r,R)} \min(\nu(x_0, y), \hat{\nu}(x_0, y)) > 0 \tag{2.8}$$

where $\overline{A}(x_0, r, R) = \{x \in \mathfrak{X} : r \leq d(x_0, x) \leq R\}$. (Here we do not require that $R < R_0$.) Indeed, we may cover $\overline{A}(x_0, r, R)$ by a finite family of balls $B(y_i, r/2)$, where $y_i \in \overline{A}(x_0, r, R)$. For $y \in B(y_i, r/2)$, $\nu(x_0, y)$ is comparable with $\nu(x_0, y_i)$, and $\hat{\nu}(x_0, y)$ is comparable with $\hat{\nu}(x_0, y_i)$.

Proposition 2.1. *If $x_0 \in \mathfrak{X}$ and $0 < r < R_0$, then*

$$c_{(2.9)}(x_0, r) = \sup_{x\in B(x_0,r)} \max(\mathbf{E}_x\tau_{B(x_0,r)}, \hat{\mathbf{E}}_x\hat{\tau}_{B(x_0,r)}) < \infty. \tag{2.9}$$

Proof. Let $B = B(x_0, r)$, $R \in (r, R_0)$, $x, y \in B$ and $F(t) = \mathbf{P}_x(\tau_B > t)$. By the definition of R_0, $m(\mathfrak{X} \setminus B(x_0, R)) > 0$. This and (2.7) yield $\nu(y, \mathfrak{X} \setminus B) \geq \nu(y, \mathfrak{X} \setminus B(x_0, R)) \geq c_{(2.7)}^{-1}\nu(x_0, \mathfrak{X} \setminus B(x_0, R)) = c$, where $c = c(x_0, r, R)$. By the Ikeda-Watanabe formula (2.5),

$$\begin{aligned} -F'(t) &= \frac{\mathbf{P}_x(\tau_B \in dt)}{dt} \geq \frac{\mathbf{P}_x(\tau_B \in dt, X_{\tau_B-} \neq X_{\tau_B}, X_{\tau_B} \in \mathfrak{X} \setminus B)}{dt} \\ &= \int_{\mathfrak{X}} \nu(y, \mathfrak{X} \setminus B)T_t^B(x, dy) \geq c\int_{\mathfrak{X}} T_t^B(x, dy) = cF(t). \end{aligned}$$

Hence $\mathbf{P}_x(\tau_B > t) \leq e^{-ct}$. If follows that $\mathbf{E}_x\tau_B \leq 1/c$. Similarly, $\hat{\mathbf{E}}_x\hat{\tau}_B \leq 1/c$. ☐

In particular, if $0 < R < R_0$ and $D \subseteq B(x_0, R)$, then the Green function $G_D(x, y)$ exists (see the discussion following Assumption A), and for each $x \in \mathfrak{X}$ it is finite for all y in $\mathfrak{X}$ less a polar set. We need to assume slightly more. The following condition may be viewed as a weak version of Harnack's inequality.

Assumption D. If $x_0 \in \mathfrak{X}$, $0 < r < p < R < R_0$ and $B = B(x_0, R)$, then

$$c_{(2.10)}(x_0, r, p, R) = \sup_{x \in B(x_0,r)} \sup_{y \in \mathfrak{X} \setminus B(x_0,p)} \max(G_B(x, y), \hat{G}_B(x, y)) < \infty. \tag{2.10}$$

Assumptions A, B, C and D are tacitly assumed throughout the entire paper. We recall them explicitly only in the statements of BHI and local maximum estimate.

When saying that a statement holds for almost every point of $\mathfrak{X}$, we refer to the measure m. The following technical result is a simple generalization of [18, Proposition II.3.2].

Proposition 2.2. *Suppose that Y_t is a standard Markov process such that for every $x \in \mathfrak{X}$ and $\alpha > 0$, the α-potential kernel $\mathcal{V}_\alpha(x, dy)$ of Y_t is absolutely continuous with respect to $m(dy)$. Suppose that function f is excessive for the transition semigroup of Y_t, and f is not identically infinite. If function g is continuous and $f(x) \le g(x)$ for* almost every *$x \in B(x_0, r)$, then $f(x) \le g(x)$ for* every *$x \in B(x_0, r)$.*

Proof. Let $A = \{x \in B(x_0, r) : f(x) > g(x)\}$. Then $m(A) = 0$, so that A is of zero potential for Y. Hence $B(x_0, r) \setminus A$ is finely dense in $B(x_0, r)$. Since $f - g$ is finely continuous, we have $f(x) \le g(x)$ for all $x \in B(x_0, r)$, as desired. (See e.g. [18, 36] for the notion of fine topology and fine continuity of excessive functions.) □

If X_t is transient, (2.10) often holds even when G_B is replaced by $G_{\mathfrak{X}} = \mathcal{U}$. In the recurrent case, we can use estimates of $\mathcal{U}_\alpha$, as follows.

Proposition 2.3. *If $x_0 \in \mathfrak{X}$, $0 < r < p < R < R_0$, $\alpha > 0$,*

$$c_1(x_0, r, p, \alpha) = \sup_{x \in B(x_0,r)} \sup_{y \in \mathfrak{X} \setminus B(x_0,p)} \max(\mathcal{U}_\alpha(x, y), \hat{\mathcal{U}}_\alpha(x, y)) < \infty,$$

and $T_t(x, dy) \le c_2(t)m(dy)$ for all $x, y \in \mathfrak{X}$, $t > 0$, then in (2.10) we may let

$$c_{(2.10)}(x_0, r, p, R) = \inf_{\alpha, t > 0} \left(e^{\alpha t} c_1(x_0, r, p, \alpha) + c_2(t) c_{(2.9)}(x_0, R) \right).$$

Proof. Denote $B = B(x_0, R)$. If $x \in B(x_0, r)$, $t_0 > 0$ and $E \subseteq B \setminus B(x_0, p)$, then

$$\begin{aligned} G_B \mathbf{1}_E(x) &= \int_0^\infty T_t^B \mathbf{1}_E(x) dt \\ &\le e^{\alpha t_0} \int_0^{t_0} e^{-\alpha t} T_t^B \mathbf{1}_E(x) dt + \int_0^\infty T_s^B (T_{t_0}^B \mathbf{1}_E)(x) ds \\ &\le e^{\alpha t_0} \int_0^\infty e^{-\alpha t} T_t \mathbf{1}_E(x) dt + \left(\sup_{y \in B} T_{t_0}^B \mathbf{1}_E(y) \right) \int_0^\infty T_s^B \mathbf{1}(y) ds \\ &\le e^{\alpha t_0} \mathcal{U}_\alpha \mathbf{1}_E(x) + \left(\sup_{y \in B} T_{t_0} \mathbf{1}_E(y) \right) G_B \mathbf{1}(x) \\ &\le (e^{\alpha t_0} c_1 + c_2 G_B \mathbf{1}(x)) |E|, \end{aligned}$$

where $c_1 = c_1(x_0, r, p, \alpha)$ and $c_2 = c_2(t_0)$. If $y \in B \setminus B(x_0, p)$, then by Proposition 2.2, $G_B(x, y) \le e^{\alpha t_0} c_1 + c_2 G_B \mathbf{1}(x)$. By Proposition 2.1, $G_B \mathbf{1}(x) = \mathbf{E}_x \tau_B \le c_{(2.9)}(x_0, R)$. The estimate of $\hat{G}_B(x, y)$ is similar. □

We use the standard notation $\mathbf{E}_x(Z; E) = \mathbf{E}_x(Z\mathbf{1}_E)$. Recall that all functions f on $\mathfrak{X}$ are automatically extended to $\mathfrak{X} \cup \{\partial\}$ by letting $f(\partial) = 0$. In particular, we understand that $\mathcal{A}f(\partial) = 0$ for all $f \in \mathcal{D}(\mathcal{A})$, and $\mathbf{E}_x\mathcal{A}f(X_\tau) = \mathbf{E}_x(\mathcal{A}f(X_\tau); \tau < \zeta)$.

The following formula obtained by Dynkin (see [39, formula (5.8)]) plays an important role. If τ is a Markov time, $\mathbf{E}_x\tau < \infty$ and $f \in \mathcal{D}(\mathcal{A})$, then

$$\mathbf{E}_x f(X_\tau) = f(x) + \mathbf{E}_x \int_0^\tau \mathcal{A}f(X_t)dt, \qquad x \in \mathfrak{X}. \tag{2.11}$$

If $f \in \mathcal{D}(\mathcal{A})$ is supported in $\mathfrak{X} \setminus D$ and $X_t \in D$ $\mathbf{P}_y$-a.s. for $t < \tau$ and $x \in \mathfrak{X}$, then

$$\begin{aligned} \mathbf{E}_x f(X_\tau) &= \mathbf{E}_x \int_0^\tau \left(\int_{\mathfrak{X}} \nu(X_t, y) f(y) m(dy) \right) dt \\ &= \int_{\mathfrak{X}} \mathbf{E}_x \left(\int_0^\tau \nu(X_t, y) dt \right) f(y) m(dy). \end{aligned} \tag{2.12}$$

Recall that a function $f \geq 0$ on $\mathfrak{X}$ is regular harmonic in an open set $D \subseteq \mathfrak{X}$ if $f(x) = \mathbf{E}_x f(X(\tau_D))$ for all $x \in \mathfrak{X}$. By the strong Markov property we then have $f(x) = \mathbf{E}_x f(X(\tau_U))$ for all open sets $U \subseteq D$. Accordingly, we call $f \geq 0$ regular subharmonic in D (for X_t), if $f(x) \leq \mathbf{E}_x f(X(\tau_U))$ for all open sets $U \subseteq D$ and all $x \in U$. We like to recall that $f \geq 0$ is called harmonic in D, if $f(x) = \mathbf{E}_x f(X(\tau_U))$ for all open and bounded U such that $\overline{U} \subseteq D$, and all $x \in U$. This condition is satisfied, e.g., by the Green function $G_D(\cdot, y)$ in $D \setminus \{y\}$, and it is weaker than regular harmonicity. In this work however, only the notion of regular harmonicity is used.

3. Boundary Harnack inequality

Recall that Assumptions A, B, C and D are in force throughout the entire paper. Some results, however, hold in greater generality. For example, the following Lemma 3.1 relies solely on Assumption B and (2.9), and it remains true also when X_t is a diffusion process. Also, Lemma 3.2 and Corollary 3.3 require Assumptions B and C but not A or D.

Lemma 3.1. *If $x_0 \in \mathfrak{X}$ and $0 < r < R < \tilde{R} < \infty$, then for all $D \subseteq B(x_0, R)$ we have*

$$\mathbf{P}_x(X_{\tau_D} \in \overline{A}(x_0, R, \tilde{R})) \leq c_{(3.1)} \mathbf{E}_x \tau_D, \qquad x \in B(x_0, r) \cap D, \tag{3.1}$$

where $c_{(3.1)} = c_{(3.1)}(x_0, r, R, \tilde{R}) = \inf_{\tilde{r} > \tilde{R}} \varrho(\overline{A}(x_0, R, \tilde{R}), A(x_0, r, \tilde{r}))$.

Proof. We fix an auxiliary number $\tilde{r} > \tilde{R}$ and $x \in B(x_0, r)$. Let $f \in \mathcal{D}$ be a bump function from Assumption B for the compact set $\overline{A}(x_0, R, \tilde{R})$ and the open set $A(x_0, r, \tilde{r})$. Thus, $f \in \mathcal{D}(\mathcal{A})$, $f(x) = 0$, $f(y) = 1$ for $y \in \overline{A}(x_0, R, \tilde{R})$ and $0 \leq f(y) \leq 1$ for all $y \in \mathfrak{X}$. By Dynkin's formula (2.11) we have

$$\mathbf{P}_x(X_{\tau_D} \in \mathfrak{X} \setminus B(x_0, R)) \leq \mathbf{E}_x(f(X_{\tau_D})) - f(x) = G_D(\mathcal{A}f)(x) \leq G_D\mathbf{1}(x) \sup_{y \in \mathfrak{X}} \mathcal{A}f(y).$$

Since $G_D\mathbf{1}(x) = \mathbf{E}_x\tau_D$, the proof is complete. □

We write $f \approx cg$ if $c^{-1}g \leq f \leq cg$. We will now clarify the relation between BHI and local supremum estimate.

Lemma 3.2. *The following conditions are equivalent:*

(a) *If $x_0 \in \mathfrak{X}$, $0 < r < R < R_0$, $D \subseteq B(x_0, R)$ is open, f is nonnegative, regular harmonic in D and vanishes in $B(x_0, R) \setminus D$, then*

$$f(x) \leq c_{(3.11)} \int_{\mathfrak{X} \setminus B(x_0, r)} f(y) \nu(x_0, y) m(dy) \tag{3.2}$$

for $x \in B(x_0, r) \cap D$, *where* $c_{(3.11)} = c_{(3.11)}(x_0, r, R)$.

(b) *If* $x_0 \in \mathfrak{X}$, $0 < r < p < q < R < R_0$, $D \subseteq B(x_0, R)$ *is open,* f *is nonnegative, regular harmonic in* D *and vanishes in* $B(x_0, R) \setminus D$, *then*

$$f(x) \approx c_{(3.3)} \mathbf{E}_x(\tau_{D \cap B(x_0,p)}) \int_{\mathfrak{X} \setminus B(x_0,q)} f(y)\nu(x_0, y)m(dy) \tag{3.3}$$

for $x \in B(x_0, r) \cap D$, *where* $c_{(3.3)} = c_{(3.3)}(x_0, r, p, q, R)$.

In fact, if (a) *holds, then we may let*

$$c_{(3.3)}(x_0, r, p, q, R) = c_{(3.1)}(x_0, r, p, q)c_{(3.11)}(x_0, q, R) + c_{(2.7)}(x_0, p, q),$$

and if (b) *holds, then we may let*

$$c_{(3.11)}(x_0, r, R) = \inf_{\substack{p,q \\ r<p<q<R}} c_{(3.3)}(x_0, r, p, q, R)c_{(2.9)}(x_0, R).$$

Proof. Since $\mathfrak{X} \setminus B(x_0, q) \subseteq \mathfrak{X} \setminus B(x_0, r)$ and $\mathbf{E}_x(\tau_{D \cap B(x_0,p)}) \le \mathbf{E}_x(\tau_{B(x_0,R)}) \le c_{(2.9)}(x_0, R)$, we see that (b) implies (a) with $c_{(3.11)} = c_{(3.3)}(x_0, r, p, q, R)c_{(2.9)}(x_0, R)$. Below we prove the converse. Let (a) hold, and $U = D \cap B(x_0, p)$. We have

$$f(x) = \mathbf{E}_x(f(X_{\tau_U}); X_{\tau_U} \in \overline{B}(x_0, q)) + \mathbf{E}_x(f(X_{\tau_U}); X_{\tau_U} \in \mathfrak{X} \setminus \overline{B}(x_0, q)). \tag{3.4}$$

Denote the terms on the right hand side by I and J, respectively. By (3.1) and (3.2),

$$\begin{aligned} 0 \le I &\le \mathbf{P}_x(X_{\tau_U} \in \overline{A}(x_0, p, q)) \sup_{y \in B(x_0,q)} f(y) \\ &\le c_{(3.1)}c_{(3.11)} \mathbf{E}_x \tau_U \int_{\mathfrak{X} \setminus B(x_0,q)} f(y)\nu(x_0, y)m(dy), \end{aligned} \tag{3.5}$$

with $c_{(3.1)}(x_0, r, p, q)$ and $c_{(3.11)}(x_0, q, R)$. For J, the Ikeda-Watanabe formula (2.12) yields

$$\begin{aligned} J &= \int_{\mathfrak{X} \setminus \overline{B}(x_0,q)} \left(\int_U G_U(x, z)\nu(z, y)f(y)m(dz) \right) m(dy) \\ &\approx c_{(2.7)} \int_{\mathfrak{X} \setminus \overline{B}(x_0,q)} \left(\int_U G_U(x, z)\nu(x_0, y)f(y)m(dz) \right) m(dy) \\ &= c_{(2.7)} \mathbf{E}_x \tau_U \int_{\mathfrak{X} \setminus \overline{B}(x_0,q)} \nu(x_0, y)f(y)m(dy), \end{aligned} \tag{3.6}$$

with constant $c_{(2.7)}(x_0, p, q)$. Formula (3.3) follows, as we have $c_{(3.1)}c_{(3.11)} + c_{(2.7)}$ in the upper bound and $1/c_{(2.7)}$ in the lower bound. ☐

We like to remark that BHI boils down to the approximate factorization (3.3) of $f(x) = \mathbf{P}_x(X(\tau_D) \in E)$. We also note that $\mathbf{P}_x(X(\tau_D) \in E) \approx \nu(x_0, E)\mathbf{E}_x\tau_D$, if E is far from $B(x_0, R)$, since then $\nu(z, E) \approx \nu(x_0, E)$ in (2.6). However, $\nu(z, E)$ in (2.6) is quite singular and much larger than $\nu(x_0, E)$ if both z and E are close to $\partial B(x_0, R)$. Our main task is to prove that the contribution to (2.6) from such points z is compensated by the relatively small time spent there by X^D_t when starting at $x \in D$. In fact, we wish to control (2.6) by an integral free from singularities (i.e. (3.2)), if x and E are not too close.

By substituting (3.3) into (1.1), we obtain the following result.

Corollary 3.3. *The conditions* (a), (b) *of Lemma* 3.2 *imply* (BHI) *with*

$$c_{(1.1)}(x_0, r, R) = \inf_{\substack{p,q \\ r<p<q<R}} (c_{(3.3)}(x_0, r, p, q, R))^4. \quad \square$$

The main technical result of the paper is the following *local supremum estimate* for subharmonic functions, which is of independent interest. The result is proved in Section 4.

Theorem 3.4. *Suppose that Assumptions A, B, C and D hold true. Let* $x_0 \in \mathfrak{X}$ *and* $0 < r < q < R < R_0$*, where* R_0 *is the localization radius from Assumptions C and D. Let function* f *be nonnegative on* $\mathfrak{X}$ *and subharmonic with respect to* X_t *in* $B(x_0, R)$*. Then*

$$f(x) \le \int_{\mathfrak{X} \setminus B(x_0,q)} f(y)\pi_{x_0,r,q,R}(y)m(dy), \qquad x \in B(x_0, r), \tag{3.7}$$

where

$$\pi_{x_0,r,q,R}(y) = \begin{cases} c_{(3.9)}\delta & \text{for } y \in B(x_0, R) \setminus B(x_0, q), \\ 2c_{(3.9)} \min(\delta, \hat{\nu}(y, B(x_0, R))) & \text{for } y \in \mathfrak{X} \setminus B(x_0, R), \end{cases} \tag{3.8}$$

$\delta = \varrho(\overline{B}(x_0, q), B(x_0, R))$ *(see Assumption B), and*

$$c_{(3.9)}(x_0, r, q, R) = \inf_{p \in (r,q)} \left(c_{(2.10)}(x_0, r, p, R) + \frac{c_{(2.9)}(x_0, R)(c_{(2.7)}(x_0, p, q))^2}{m(B(x_0, p))} \right). \tag{3.9}$$

Theorem 3.4 (to be proved in the next section) and Corollary 3.3 lead to BHI. We note that no regularity of the open set D is assumed.

Theorem 3.5. *If assumptions A, B, C and D are satisfied, then (BHI) holds true with*

$$c_{(1.1)}(x_0, r, R) = \inf_{\substack{p,q,\tilde{r} \\ r<p<q<R<\tilde{r}}} \left(\varrho(\overline{A}(x_0, p, q), A(x_0, r, \tilde{r}))c_{(3.11)}(x_0, q, R) + c_{(2.7)}(x_0, p, q) \right)^4, \tag{3.10}$$

$$\begin{aligned} c_{(3.11)}(x_0, q, R) = \inf_{\substack{\tilde{q},\tilde{R} \\ q<\tilde{q}<R<\tilde{R}}} \; & 2c_{(3.9)}(x_0, q, \tilde{q}, R)\times \\ & \times \max\left(\frac{\varrho(\overline{B}(x_0, \tilde{q}), B(x_0, R))}{c_{(2.8)}(x_0, \tilde{q}, \tilde{R})}, c_{(2.7)}(x_0, R, \tilde{R})m(B(x_0, R)) \right). \end{aligned} \tag{3.11}$$

Proof. We only need to prove condition (a) of Lemma 3.2. Let $q, \tilde{R}$ satisfy $r < q < R < \tilde{R}$. By (3.7) and (3.8) of Theorem 3.4, it suffices to prove that $\pi_{x_0,r,q,R}(y) \le c_{(3.11)}\nu(x_0, y)$. For $y \in \overline{A}(x_0, q, \tilde{R})$ we have

$$\pi_{x_0,r,q,R}(y) \le 2c_{(3.9)}\delta \le \frac{2c_{(3.9)}\delta}{c_{(2.8)}} \nu(x_0, y),$$

with $c_{(2.8)} = c_{(2.8)}(x_0, q, \tilde{R})$. If $y \in \mathfrak{X} \setminus \overline{B}(x_0, \tilde{R})$, then

$$\pi_{x_0,r,q,R}(y) \le 2c_{(3.9)}\hat{\nu}(y, B(x_0, R)) \le 2c_{(3.9)}c_{(2.7)}m(B(x_0, R))\nu(x_0, y),$$

with $c_{(2.7)} = c_{(2.7)}(x_0, R, \tilde{R})$. The proof is complete. □

Remark 3.6. (BHI) is said to be *scale-invariant* if $c_{(1.1)}$ may be so chosen to depend on r and R only through the ratio r/R. In some applications, the property plays a crucial role, see, e.g., [14, 26]. If X_t admits *stable-like scaling*, then $c_{(1.1)}$ given by (3.10) is scale-invariant indeed, as explained in Section 5 (see Theorem 5.4).

Remark 3.7. The constant $c_{(1.1)}$ in Theorem 3.5 depends only on basic characteristics of X_t. Accordingly, in Section 5 it is shown that BHI is stable under small perturbations.

Remark 3.8. BHI applies in particular to hitting probabilities: if $0 < r < R < R_0$, $x, y \in B(x_0, r) \cap D$ and $E_1, E_2 \subseteq \mathfrak{X} \setminus B(x_0, R)$, then

$$\mathbf{P}_x(X_{\tau_D} \in E_1)\mathbf{P}_y(X_{\tau_D} \in E_2) \le c_{(1.1)}\, \mathbf{P}_y(X_{\tau_D} \in E_1)\mathbf{P}_x(X_{\tau_D} \in E_2).$$

Remark 3.9. BHI implies the usual Harnack inequality if, e.g., constants are harmonic.

The approach to BHI via approximate factorization was applied to isotropic stable processes in [26], to stable-like subordinate diffusion on the Sierpiński gasket in [53], and to a wide class of isotropic Lévy processes in [63]. In all these papers, the taming of the intensity of jumps near the boundary was a crucial step. This parallels the connection of the Carleson estimate and BHI in the classical potential theory, see Section 1.

4. REGULARIZATION OF THE EXIT DISTRIBUTION

In this section we prove Theorem 3.4. The proof is rather technical, so we begin with a few words of introduction and an intuitive description of the idea of the proof.

In [26, Lemma 6], an analogue of Theorem 3.4 was obtained for the isotropic α-stable Lévy processes by averaging harmonic measure of the ball against the variable radius of the ball. The procedure yields a kernel with no singularities and a mean value property for harmonic functions. In the setting of [26] the boundedness of the kernel follows from the explicit formula and bounds for the harmonic measure of a ball. A similar argument is classical for harmonic functions of the Laplacian and the Brownian motion. For more general processes X_t this approach is problematic: while the Ikeda-Watanabe formula gives precise bounds for the harmonic measure far from the ball, satisfactory estimates near the boundary of the ball require exact decay rate of the Green function, which is generally unavailable. In fact, resolved cases indicate that sharp estimates of the Green function are equivalent to BHI ([20]), hence not easier to obtain. Below we use a different method to mollify the harmonic measure.

Recall that the harmonic measure of B is the distribution of $X(\tau_B)$. It may be interpreted as the mass lost by a particle moving along the trajectory of X_t, when it is killed at the moment τ_B. In the present paper we let the particle lose the mass *gradually* before time τ_B, with intensity $\psi(X_t)$ for a suitable function $\psi \geq 0$ sharply increasing at ∂B. The resulting distribution of the lost mass defines a kernel with a mean value property for harmonic functions, and it is less singular than the distribution of $X(\tau_B)$.

Throughout this section, we fix $x_0 \in \mathfrak{X}$ and four numbers $0 < r < p < q < R < R_0$, where R_0 is defined in Assumptions C and D. For the compact set $\overline{B}(x_0, q)$ and the open set $B(x_0, R)$ we consider the bump function φ provided by Assumption B. We let

$$\delta = \sup_{x\in\mathfrak{X}} \max(\mathcal{A}\varphi(x), \hat{\mathcal{A}}\varphi(x)), \tag{4.1}$$

and

$$V = \{x \in \mathfrak{X} : \varphi(x) > 0\}. \tag{4.2}$$

We have $V \subseteq B(x_0, R)$, see Figure 1. By Assumption B, $m(\partial V) = 0$. Note that $\mathcal{A}\varphi(x) \leq 0$ and $\hat{\mathcal{A}}\varphi(x) \leq 0$ if $x \in B(x_0, q)$, and δ can be arbitrarily close to $\varrho(\overline{B}(x_0, q), B(x_0, R))$.

We consider a function $\psi : \mathfrak{X} \cup \{\partial\} \to [0, \infty]$ continuous in the extended sense and such that $\psi(x) = \infty$ for $x \in (\mathfrak{X} \setminus V) \cup \{\partial\}$, and $\psi(x) < \infty$ when $x \in V$. Let

$$A_t = \lim_{\varepsilon \searrow 0} \int_0^{t+\varepsilon} \psi(X_s) ds, \qquad t \geq 0. \tag{4.3}$$

We see that A_t is a right-continuous, strong Markov, nonnegative (possibly infinite) additive functional, and $A_t = \infty$ for $t \geq \zeta$. We denote by M_t the right-continuous multiplicative functional

$$M_t = e^{-A_t}.$$

For $a \in [0, \infty]$, we let τ_a be the first time when $A_t \geq a$. In particular, τ_∞ is the time when A_t becomes infinite. Note that A_t and M_t are continuous except perhaps at the

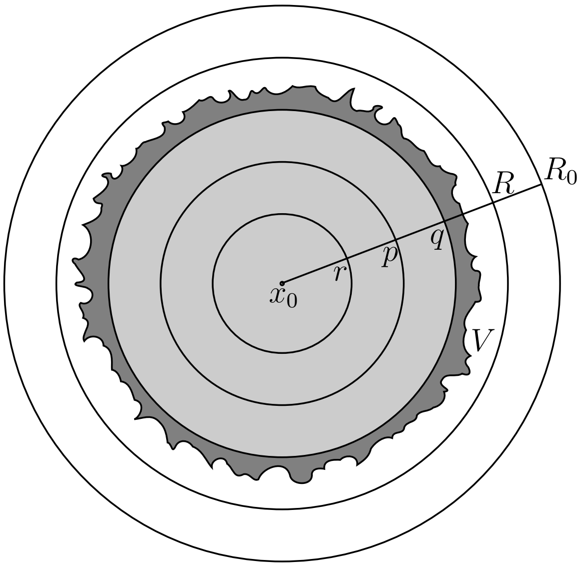

FIGURE 1. Notation for Section 4.

single (random) moment τ_∞ when A_t becomes infinite and the left limit $A(\tau_\infty-)$ is finite. Since A_t is finite for $t < \tau_V$, we have $\tau_\infty \ge \tau_V$. If ψ grows sufficiently fast near ∂V, then in fact $\tau_\infty = \tau_V$, as we shall see momentarily.

Lemma 4.1. *If $c_1, c_2 > 0$ are such that $\psi(x) \ge c_1(\varphi(x))^{-1} - c_2$ for all $x \in V$, then $A(\tau_V) = \infty$ and $M(\tau_V) = 0$ $\mathbf{P}_x$-a.s. for every $x \in \mathfrak{X}$. In particular, $\tau_V = \tau_\infty$.*

Proof. We first assume that $x \in \mathfrak{X} \setminus V$. In this case it suffices to prove that $A_0 = \infty$. Since $\mathcal{A}\varphi(y) \le \delta$ for all $y \in \mathfrak{X}$, and $\varphi(x) = 0$, from Dynkin's formula for the (deterministic) time s it follows that $\mathbf{E}_x(\varphi(X_s)) \le \delta s$ for all $s > 0$. By the Schwarz inequality,

$$\left(\int_\varepsilon^t \frac{1}{s} \, ds \right)^2 \le \left(\int_\varepsilon^t \frac{\varphi(X_s)}{s^2} \, ds \right) \left(\int_\varepsilon^t \frac{1}{\varphi(X_s)} \, ds \right),$$

where $0 < \varepsilon < t$. Here we use the conventions $1/0 = \infty$ and $0 \cdot \infty = \infty$. Thus,

$$\begin{aligned} \mathbf{E}_x \left(\int_\varepsilon^t \frac{1}{\varphi(X_s)} \, ds \right)^{-1} &\le \left(\int_\varepsilon^t \frac{1}{s} \, ds \right)^{-2} \mathbf{E}_x \left(\int_\varepsilon^t \frac{\varphi(X_s)}{s^2} \, ds \right) \\ &\le \left(\int_\varepsilon^t \frac{1}{s} \, ds \right)^{-2} \int_\varepsilon^t \frac{\delta}{s} \, ds = \frac{\delta}{\log(t/\varepsilon)} \, , \end{aligned}$$

with the convention $1/\infty = 0$. Hence,

$$\begin{aligned} \mathbf{E}_x \left(\frac{1}{A_t + c_2 t} \right) &\le \mathbf{E}_x \left(\int_\varepsilon^t (\psi(X_s) + c_2) ds \right)^{-1} \\ &\le \mathbf{E}_x \left(\int_\varepsilon^t \frac{c_1}{\varphi(X_s)} \, ds \right)^{-1} \le \frac{\delta}{c_1 \log(t/\varepsilon)} \, . \end{aligned} \tag{4.4}$$

By taking $\varepsilon \searrow 0$, we obtain

$$\mathbf{E}_x \left(\frac{1}{A_t + c_2 t} \right) = 0.$$

It follows that $A_t = \infty$ $\mathbf{P}_x$-a.s. We conclude that $A_0 = \infty$ and $M_0 = 0$ $\mathbf{P}_x$-a.s., as desired.

When $x \in V$, the result in the statement of the lemma follows from the strong Markov property. If $M(\tau_V-)$ denotes the left limit of M_t at $t = \tau_V$, then

$$\mathbf{E}_x M_{\tau_V} = \mathbf{E}_x(M_{\tau_V-}\mathbf{E}_{X(\tau_V)}(M_0)) = 0,$$

by the first part of the proof,. The lemma is proved. $\square$

From now on we only consider the case when the assumptions of Lemma 4.1 are satisfied, and c_1, c_2 are reserved for the constants in the condition $\psi(x) \geq c_1(\varphi(x))^{-1} - c_2$. By the definition and right-continuity of paths of X_t, A_t and M_t are monotone right-differentiable continuous functions of t on $[0, \tau_V)$, with derivatives $\psi(X_t)$ and $-\psi(X_t)M_t$, respectively.

Let $\varepsilon_a(\cdot)$ be the Dirac measure at a. Lemma 4.1 yields the following result.

Corollary 4.2. *We have* $-dM_t = \psi(X_t)M_t dt + M(\tau_V-)\varepsilon_{\tau_V}(dt)$ $\mathbf{P}_x$*-a.s. In particular,*

$$-\mathbf{E}_x \int_{[0,\tau)} f(X_t)dM_t = \mathbf{E}_x \left(\int_0^\tau f(X_t)\psi(X_t)M_t dt \right) + \mathbf{E}_x \left(M_{\tau_V-} f(X_{\tau_V}); \tau > \tau_V \right) \tag{4.5}$$

for any measurable random time τ *and nonnegative or bounded function* f. $\square$

We emphasize that if M_t has a jump at τ, in which case we must have $\tau = \tau_V$, then the jump does not contribute to the Lebesgue-Stieltjes integral $\int_{[0,\tau)} f(X_t)dM_t$ in (4.5). The same remark applies to (4.6) below.

Recall that $\tau_a = \inf\{t \geq 0 : A_t \geq a\}$. Note that τ_a are Markov times for X_t, $a \mapsto \tau_a$ is the left-continuous inverse of $t \mapsto A_t$, and the events $\{t < \tau_a\}$ and $\{A_t < a\}$ are equal. We have $A(\tau_a) = a$ unless $\tau_a = \tau_V$, and, clearly, $\tau_a \leq \tau_\infty = \tau_V$.

The following may be considered as an extension of Dynkin's formula.

Lemma 4.3. *For* $f \in \mathcal{D}(\mathcal{A})$*, Markov time* τ*, and* $x \in V$*, we have*

$$\mathbf{E}_x \int_0^\tau \mathcal{A}f(X_t)M_t dt = \mathbf{E}_x(f(X_\tau)M_{\tau-}) - f(x) - \mathbf{E}_x \int_{[0,\tau)} f(X_t)dM_t. \tag{4.6}$$

If $g = (\mathcal{A} - \psi)f$ *and* $\tau \leq \tau_V$*, then*

$$\mathbf{E}_x \int_0^\tau g(X_t)M_t dt = \mathbf{E}_x(f(X_\tau)M_{\tau-}) - f(x). \tag{4.7}$$

In fact, (4.6) *holds for every strong Markov right-continuous multiplicative functional* M_t.

Proof. Since $\int_{A_t}^\infty e^{-a}da = M_t$ and $\{t < \tau_a\} = \{A_t < a\}$, by Fubini,

$$\begin{aligned} \mathbf{E}_x \int_0^\tau \mathcal{A}f(X_t)M_t dt &= \mathbf{E}_x \int_0^\tau \mathcal{A}f(X_t) \left(\int_0^\infty \mathbf{1}_{(0,\tau_a)}(t)e^{-a}da \right) dt \\ &= \int_0^\infty \left(\mathbf{E}_x \int_0^{\min(\tau,\tau_a)} \mathcal{A}f(X_t)dt \right) e^{-a}da. \end{aligned}$$

Since $\min(\tau, \tau_a)$ is a Markov time for X_t, we can apply Dynkin's formula. It follows that

$$\mathbf{E}_x \int_0^{\min(\tau,\tau_a)} \mathcal{A}f(X_t)M_t dt = \mathbf{E}_x(f(X_{\min(\tau,\tau_a)})) - f(x).$$

By Fubini and the substitution $\tau_a = t$, $a = A_t$, $e^{-a} = M_t$,

$$\begin{aligned}\mathbf{E}_x \int_0^\tau \mathcal{A}f(X_t)M_t dt &= \int_0^\infty \left(\mathbf{E}_x(f(X_{\min(\tau,\tau_a)})) - f(x)\right) e^{-a} da \\ &= \mathbf{E}_x \left(\int_0^\infty f(X_{\min(\tau,\tau_a)}) e^{-a} da\right) - f(x) \\ &= -\mathbf{E}_x \left(\int_{[0,\infty)} f(X_{\min(\tau,t)}) dM_t\right) - f(x).\end{aligned}$$

We emphasize that the last equality holds true also if $\tau = \tau_V$ with positive probability. We see that (4.6) holds. By (4.5) we obtain (4.7). □

The functional M_t is a Feynman-Kac functional, interpreted as the diminishing mass of a particle started at $x \in \mathfrak{X}$. We shall estimate the kernel $\pi_\psi(x, dy)$, defined as the expected amount of mass left by the particle at dy. Namely, for any nonnegative or bounded f we define

$$\pi_\psi f(x) = -\mathbf{E}_x \int_{[0,\infty)} f(X_t) dM_t, \qquad x \in \mathfrak{X}. \tag{4.8}$$

Note that $\pi_\psi f(x) = f(x)$ for $x \in \mathfrak{X} \setminus V$. By the substitution $\tau_a = t$, $a = A_t$, $e^{-a} = M_t$ and Fubini, we obtain that

$$\pi_\psi f(x) = \mathbf{E}_x \left(\int_0^\infty f(X_{\tau_a}) e^{-a} da\right) = \int_0^\infty \mathbf{E}_x(f(X_{\tau_a})) e^{-a} da. \tag{4.9}$$

The potential kernel $G_\psi(x, dy)$ of the functional M_t will play an important role. Namely, for any nonnegative or bounded f we let

$$G_\psi f(x) = \mathbf{E}_x \int_0^\infty f(X_t) M_t dt = \mathbf{E}_x \int_0^\infty \left(\int_0^{\tau_a} f(X_t) dt\right) e^{-a} da. \tag{4.10}$$

In the second equality above, the identities $M_t = \int_{A_t}^\infty e^{-a} da$ and $\{t < \tau_a\} = \{A_t < a\}$ were used together with Fubini, as in the proof of Lemma 4.3. We note that $G_\psi(x, dy)$ measures the expected time spent by the process X_t at dy, weighted by the decreasing mass of X_t (compare with the similar role of $G_V(x, y)m(dy)$). There is a semigroup of operators $T_t^\psi f(x) = \mathbf{E}_x(f(X_t)M_t)$ associated with the multiplicative functional M_t. Furthermore, T_t^ψ are transition operators of a Markov process X_t^ψ, the *subprocess* of X_t corresponding to M_t. With the definitions of [18], M_t is a strong Markov right-continuous multiplicative functional and V is the set of permanent points for M_t. Therefore, X_t^ψ is a standard Markov process with state space V, see [18, III.3.12, III.3.13 and the discussion after III.3.17]. (From (4.4) and [18, Proposition III.5.9] it follows that M_t is an exact multiplicative functional. Furthermore, since M_t can be discontinuous only at $t = \tau_V$, the functional M_t is quasi-left continuous in the sense of [18, III.3.14], and therefore X_t^ψ is a Hunt process on V. However, we do not use these properties in our development.)

Informally, X_t^ψ is obtained from X_t by terminating the paths of X_t with rate $\psi(X_t)dt$, and $\pi_\psi(x, dy)$ is the distribution of X_t stopped at the time when X_t^ψ is killed. Furthermore, $G_\psi(x, dy)$ is the potential kernel of X_t^ψ. To avoid technical difficulties related to subprocesses and the domains of their generators, in what follows we rely mostly on the formalism of additive and multiplicative functionals.

The dual multiplicative functional $\hat{M}_t$ is defined just as M_t, but for the dual process $\hat{X}_t$. We correspondingly define $\hat{\pi}_\psi$ and $\hat{G}_\psi$. The subprocess $\hat{X}_t^\psi$ of $\hat{X}_t$ corresponding to the multiplicative functional $\hat{M}_t$ is the dual process of X_t^ψ; see [36, 13.6 and Remark 13.26].

Hence, the potential kernel G_ψ of X_t^ψ admits a uniquely determined density function $G_\psi(x,y)$ $(x,y \in V)$, which is excessive in x with respect to the transition semigroup T_t^ψ of X_t^ψ, and excessive in y with respect to the transition semigroup $\hat{T}_t^\psi$ of $\hat{X}_t^\psi$. Furthermore, $\hat{G}_\psi(x,y) = G_\psi(y,x)$ is the density of the potential kernel of $\hat{X}_t^\psi$. Since $G_\psi(x,dy)$ is concentrated on V, we let $G_\psi(x,y) = 0$ if $x \in \mathfrak{X} \setminus V$ or $y \in \mathfrak{X} \setminus V$. Clearly, $G_\psi(x,dy)$ is dominated by $G_V(x,dy)$ for all $x \in V$, and therefore

$$G_\psi(x,y) \le G_V(x,y), \quad x,y \in \mathfrak{X}.$$

There are important relations between π_ψ, G_ψ, ψ and $\mathcal{A}$. If f is nonnegative or bounded and *vanishes* in $\mathfrak{X} \setminus V$, then by Corollary 4.2 we have

$$\pi_\psi f(x) = G_\psi(\psi f)(x), \qquad x \in V. \tag{4.11}$$

Considering $\tau = \tau_V$, we note that $M(\tau_V) = 0$, and so for bounded or nonnegative f

$$\int_{[0,\tau_V]} f(X_t)dM_t = \int_{[0,\tau_V)} f(X_t)dM_t - f(X_{\tau_V})M_{\tau_V-}.$$

If $f \in \mathcal{D}(\mathcal{A})$, then formula (4.6) gives

$$G_\psi \mathcal{A} f(x) = \pi_\psi f(x) - f(x), \qquad x \in V. \tag{4.12}$$

Furthermore, by (4.7), for $f \in \mathcal{D}(\mathcal{A})$ we have

$$G_\psi(\mathcal{A} - \psi)f(x) = \mathbf{E}_x(f(X_{\tau_V})M_{\tau_V-}) - f(x), \qquad x \in V.$$

In particular, if $f \in \mathcal{D}(\mathcal{A})$ vanishes outside of V, then we have

$$G_\psi(\mathcal{A} - \psi)f(x) = -f(x), \qquad x \in V \tag{4.13}$$

(which also follows directly from (4.11) and (4.12)). Formula (4.13) means that the generator of X_t^ψ agrees with $\mathcal{A} - \psi$ on the intersection of the respective domains.

We now introduce the Green operators G_U^ψ and harmonic measures π_U^ψ for X_t^ψ. Let U be an open subset of V. For nonnegative or bounded f and $x \in V$ we let

$$\pi_U^\psi f(x) = \mathbf{E}_x(f(X_{\tau_U})M_{\tau_U-}), \qquad G_U^\psi f(x) = \mathbf{E}_x \int_0^{\tau_U} f(X_t)M_t dt.$$

We note that $G_V^\psi f = G_\psi f$. Also, $\pi_V^\psi f = \pi_\psi f$, if f vanishes in V. Furthermore, G_U^ψ admits a density function $G_U^\psi(x,y)$, and we have $G_U^\psi(x,y) \le G_U(x,y)$, $G_U^\psi(x,y) \le G_\psi(x,y)$. If f vanishes outside of V, then we can replace $M(\tau_U-)$ by $M(\tau_U)$ in the definition of π_U^ψ. By (4.7), for any $f \in \mathcal{D}(\mathcal{A})$ we have

$$\pi_U^\psi f(x) = G_U^\psi(\mathcal{A} - \psi)f(x) + f(x), \qquad x \in V. \tag{4.14}$$

In particular, by an approximation argument,

$$\pi_U^\psi(x,E) = \int_U G_U^\psi(x,y)\nu(y,E)m(dy), \qquad x \in U,\ E \subseteq \mathfrak{X} \setminus \overline{U}. \tag{4.15}$$

Formulas (4.14) and (4.15) can be viewed correspondingly as Dynkin's formula applied to the first exit time, and the Ikeda-Watanabe formula for X_t^ψ.

Recall that $x_0 \in \mathfrak{X}$, $0 < r < p < q < R < R_0$, $B(x_0,q) \subseteq V \subseteq B(x_0,R)$, see Figure 1, $\varphi \in \mathcal{D}$ is positive in V and vanishes in $\mathfrak{X} \setminus V$, and $\varphi(x) = 1$ for $x \in B(x_0,q)$.

Lemma 4.4. *Let $U = V \setminus \overline{B}(x_0,q)$. If $(\mathcal{A} - \psi)\varphi(x) \le 0$ for $x \in V$, then*

$$\pi_U^\psi(x, V \setminus U) \le \varphi(x), \qquad x \in U. \tag{4.16}$$

Proof. By (4.14), for $x \in U$ we have

$$\pi_U^\psi \varphi(x) - \varphi(x) = G_U^\psi (\mathcal{A} - \psi)\varphi(x) \le 0.$$

It remains to note that $\varphi = 1$ on $V \setminus U$. □

Essentially, we use here (and later on) superharmonicity of φ with respect to $\mathcal{A} - \psi$.

Lemma 4.5. *If* $(\mathcal{A} - \psi)\varphi(x) \le 0$ *for* $x \in V$, *then*

$$G_\psi(x,y) \le c_{(4.17)}\varphi(x), \qquad x \in V \setminus B(x_0,p),\ y \in B(x_0,r), \tag{4.17}$$

with $c_{(4.17)} = c_{(4.17)}(x_0,r,p,q,R)$.

Proof. Let $U = V \setminus \overline{B}(x_0,q)$ and $x \in U$. Let f be a nonnegative function supported in $B(x_0,r)$, $\int f(y)m(dy) = 1$ and $g(z) = G_\psi f(z)$ (this is done to regularize $G_\psi(x,y)$). Using the definition of G_ψ, the relation $f(X_t) = 0$ for $t < \tau_U$ and the strong Markov property, we obtain that

$$g(x) = \mathbf{E}_x \left(\int_{\tau_U}^\infty f(X_t) M_t dt \right) = \mathbf{E}_x (g(X_{\tau_U}) M_{\tau_U}) = \pi_U^\psi g(x).$$

We split the last expectation into two parts, corresponding to the events $X(\tau_U) \in B(x_0,p)$ and $X(\tau_U) \in \overline{A}(x_0,p,q)$ respectively. By (2.10) and the inequality $M(\tau_U) \le 1$, we have $g(z) \le c_{(2.10)}(x_0,r,p,R)$ for $z \in \overline{A}(x_0,p,q)$. From (4.16) it follows that

$$\pi_U^\psi (g \mathbf{1}_{\overline{A}(x_0,p,q)})(x) \le c_{(2.10)} \pi_U^\psi (x, \overline{B}(x_0,q)) \le c_{(2.10)} \varphi(x). \tag{4.18}$$

For the other part, we use (4.15) and (2.7),

$$\begin{aligned} \pi_U^\psi (g \mathbf{1}_{B(x_0,p)})(x) &= \int_U \left(\int_{B(x_0,p)} g(z) \nu(y,z) m(dz) \right) G_U^\psi (x,y) m(dy) \\ &\le c_{(2.7)} \int_U \nu(y,x_0) G_U^\psi (x,y) m(dy) \cdot \int_{B(x_0,p)} g(z) m(dz), \end{aligned}$$

with constant $c_{(2.7)}(x_0,p,q)$. Using again (2.7) and (4.15), and then (4.16), we obtain

$$\begin{aligned} \int_U \nu(y,x_0) G_U^\psi (x,y) m(dy) &\le \frac{c_{(2.7)}}{m(B(x_0,p))} \int_U \nu(y, B(x_0,p)) G_U^\psi (x,y) m(dy) \\ &= \frac{c_{(2.7)}}{m(B(x_0,p))} \pi_U^\psi (x, B(x_0,p)) \le \frac{c_{(2.7)} \varphi(x)}{m(B(x_0,p))} . \end{aligned}$$

By (2.9), we have

$$\begin{aligned} \int_{B(x_0,p)} g(z) m(dz) &\le \int_{B(x_0,r)} \left(\int_{B(x_0,p)} G_V(z,y) m(dz) \right) f(y) m(dy) \\ &\le \int_{B(x_0,r)} \hat{\mathbf{E}}_y (\hat{\tau}_V) f(y) m(dy) \le c_{(2.9)}, \end{aligned}$$

with constant $c_{(2.9)}(x_0,R)$. Hence,

$$\pi_U^\psi (g \mathbf{1}_{B(x_0,p)})(x) \le \frac{(c_{(2.7)})^2 c_{(2.9)} \varphi(x)}{m(B(x_0,p))} .$$

This and (4.18) yield that $g(x) \le c_{(4.17)}\varphi(x)$, where

$$c_{(4.17)}(x_0,r,p,q,R) = c_{(2.10)}(x_0,r,p,R) + \frac{c_{(2.9)}(x_0,R)(c_{(2.7)}(x_0,p,q))^2}{m(B(x_0,p))} .$$

Recall that $g = G_\psi f$, where f is an arbitrary nonnegative function vanishing outside $B(x_0, r)$ with integral equal to 1. Hence, by approximation, for each $x \in \mathfrak{X} \setminus \overline{B}(x_0, q)$, formula (4.17) holds for *almost every* $y \in B(x_0, r)$. By Proposition 2.2 (applied to X^ψ_t), (4.17) holds for *every* $y \in B(x_0, r)$.

For $x \in \overline{A}(x_0, p, q)$, the result follows easily from (2.10). Indeed, we have $G_\psi(x, y) \le G_V(x, y) \le c_{(2.10)} = c_{(2.10)}\varphi(x)$, with constant $c_{(2.10)}(x_0, r, p, R)$. Hence, formula (4.17) holds also for $x \in \overline{A}(x_0, p, q)$, with the same constant. □

The above arguments can be repeated for the dual process $\hat{X}_t$. Hence, the *dual* versions of Lemmas 4.4 and 4.5 hold true, with the same $c_{(4.17)}$.

We are very close to the estimate of $\pi_\psi(x, dy)$ for $x \in B(x_0, r)$. Indeed, for $y \in V$ we have $\pi_\psi(x, dy) = G_\psi(x, y)\psi(y)m(dy)$ (see (4.11)). When $y \in \mathfrak{X} \setminus \overline{V}$, then, at least heuristically, $\pi_\psi(x, dy) = \hat{\mathcal{A}} G^x_\psi(y)m(dy)$, where $G^x_\psi(y) = G_\psi(x, y)$ vanishes outside of V (see (4.12)). This will give satisfactory bounds when $y \in \mathfrak{X} \setminus V$. Before we proceed, we first show that $\pi_\psi(x, \partial V) = 0$.

Lemma 4.6. *Suppose that for some $c_3, c_4 > 0$, we have $\psi(x) \ge c_3 + (\varphi(x))^{-1}\hat{\mathcal{A}}\varphi(x)$ and $\psi(x) \le c_4/\varphi(x)$ for $x \in V$. Then for every nonnegative function f we have*

$$c_3 \int_V \pi_\psi f(x)\varphi(x)m(dx) \le c_4 \int_V f(x)m(dx) + \int_{\mathfrak{X}\setminus V} f(x)\hat{\mathcal{A}}\varphi(x)m(dx). \tag{4.19}$$

Proof. First, suppose that $f \in \mathcal{D}(\mathcal{A})$. Denote $h(x) = -(\hat{\mathcal{A}} - \psi)\varphi(x)$ for $x \in V$. Note that h is nonnegative. Let $g(x) = \pi_\psi f(x)$ for $x \in \mathfrak{X}$; hence $g(x) = f(x)$ for $x \in \mathfrak{X} \setminus V$, see (4.8). By (4.12), we have $g(x) = f(x) + G_\psi \mathcal{A} f(x)$ for $x \in V$. Hence,

$$\int_V g(x)h(x)m(dx) = \int_V f(x)h(x)m(dx) + \int_V G_\psi \mathcal{A} f(x)h(x)m(dx).$$

For the second term, we have

$$\int_V G_\psi \mathcal{A} f(x)h(x)m(dx) = \int_V \mathcal{A} f(x)\hat{G}_\psi h(x)m(dx).$$

By (4.13) (dual version), $\hat{G}_\psi h(x) = -\hat{G}_\psi(\hat{\mathcal{A}} - \psi)\varphi(x) = \varphi(x)$ for $x \in V$. Hence,

$$\int_V G_\psi \mathcal{A} f(x)h(x)m(dx) = \int_V \mathcal{A} f(x)\varphi(x)m(dx) = \int_{\mathfrak{X}} f(x)\hat{\mathcal{A}}\varphi(x)m(dx).$$

In the last equality, we used the fact that $\varphi(x) = 0$ for $x \in \mathfrak{X} \setminus V$. It follows that

$$\int_V g(x)h(x)m(dx) = \int_V f(x)h(x)m(dx) + \int_{\mathfrak{X}} f(x)\hat{\mathcal{A}}\varphi(x)m(dx).$$

But $h(x) = -(\hat{\mathcal{A}} - \psi)\varphi(x)$, so that finally, after simplification,

$$\int_V g(x)h(x)m(dx) = \int_V f(x)\varphi(x)\psi(x)m(dx) + \int_{\mathfrak{X}\setminus V} f(x)\hat{\mathcal{A}}\varphi(x)m(dx).$$

Using the inequalities $\psi(x)\varphi(x) \le c_4$ for $x \in V$ and $h(x) = \psi(x)\varphi(x) - \hat{\mathcal{A}}\varphi(x) \ge c_3\varphi(x)$ for $x \in V$, we obtain (4.19). The general case of nonnegative f (not necessarily in $\mathcal{D}(\mathcal{A})$) follows by approximation. □

Lemma 4.7. *Suppose that for some $c_3, c_4 > 0$, we have $\psi(x) \ge c_3 + (\varphi(x))^{-1}\hat{\mathcal{A}}\varphi(x)$ and $\psi(x) \le c_4/\varphi(x)$ for $x \in V$. Then $M(\tau_V -)\mathbf{1}_{\partial V}(X(\tau_V)) = 0$ $\mathbf{P}_x$-a.s. and $\pi_\psi(x, \partial V) = 0$ for all $x \in V$.*

Proof. For $x \in V$ define $g(x) = \pi_\psi(x, \partial V)$. By (4.19), $\int_V g(x)\varphi(x)m(dx) = 0$, so that g vanishes almost everywhere in V. We claim that g is excessive for the transition semigroup T_t^ψ of X_t^ψ. Indeed, we have $g(x) = \mathbf{E}_x(M(\tau_V-); X(\tau_V) \in \partial V)$, so that by the Markov property, for any $t > 0$ and $x \in V$,

$$\mathbf{E}_x(M_t g(X_t)) = \mathbf{E}_x(M_t g(X_t); t < \tau_V) = \mathbf{E}_x(M_{\tau_V-}; X_{\tau_V} \in \partial V, \, t < \tau_V).$$

The right-hand side does not exceed $g(x)$, and by monotone convergence, it converges to $g(x)$ as $t \searrow 0$. Hence g is an excessive function equal to zero almost everywhere in V. By [18], Proposition II.3.2 (or by Proposition 2.2), $g(x) = 0$ for all $x \in V$. □

Recall that according to the remark following Lemma 4.1, we keep assuming that $\psi(x) \ge c_1(\varphi(x))^{-1} - c_2$ for $x \in V$. Consider $\tilde{\psi}(x) = c_1^{-1}\delta(\psi(x) + c_2) + c_3$ for some $c_3 > 0$, and let $\tilde{M}_t$ be the multiplicative functional defined in a similar manner as M_t, but with ψ replaced by $\tilde{\psi}$. Clearly, for all $t > 0$ we have $M_t = 0$ if and only if $\tilde{M}_t = 0$. Since $\tilde{\psi}(x) \ge c_3 + \delta/\varphi(x)$, an application of Lemma 4.7 to $\tilde{\psi}$ yields the following result.

Corollary 4.8. *Suppose that for some $c > 0$, we have $\psi(x) \le c/\varphi(x)$ for $x \in V$. Then $M(\tau_V-)\mathbf{1}_{\partial V}(X(\tau_V)) = 0$ $\mathbf{P}_x$-a.s. for $x \in V$. In particular, $\pi_\psi(x, \partial V) = 0$ for $x \in V$.* □

Now we make the actual choice of ψ.

Lemma 4.9. *Let δ be given by (4.1), and*

$$\psi(x) = \frac{\max(\mathcal{A}\varphi(x), \hat{\mathcal{A}}\varphi(x), \delta(1 - \varphi(x)))}{\varphi(x)}, \qquad x \in \mathfrak{X} \cup \{\partial\}, \tag{4.20}$$

where $1/0 = \infty$. For all $x \in B(x_0, r)$ we have $\pi_\psi(x, dy) \le \tilde{\pi}_\psi(y)m(dy)$, where

$$\tilde{\pi}_\psi(y) = c_{(4.17)} \left(\delta \mathbf{1}_{V \setminus B(x_0,q)}(y) + 2\min(\delta, \hat{\nu}(y, V))\mathbf{1}_{\mathfrak{X} \setminus V}(y)\right) \tag{4.21}$$

with $c_{(4.17)} = c_{(4.17)}(x_0, r, p, q, R)$ given in Lemma 4.5.

Proof. Note that $\psi(x) \ge \delta(\varphi(x))^{-1} - \delta$, $(\mathcal{A} - \psi)\varphi(x) \le 0$, $(\hat{\mathcal{A}} - \psi)\varphi(x) \le 0$ and $\psi(x) \le \delta/\varphi(x)$ for $x \in V$. Hence, we may apply Lemmas 4.1, 4.4 and 4.5, Corollary 4.8, and their dual versions. By Corollary 4.8, $\pi_\psi(x, \partial V) = 0$ for all $x \in V$. Since $\mathcal{A}\varphi(x) \le 0$ and $\hat{\mathcal{A}}\varphi(x) \le 0$ for $x \in B(x_0, q)$, we have $\psi(x) = 0$ for $x \in B(x_0, q)$, and therefore $\pi_\psi(x, B(x_0, q)) = 0$ for all $x \in V$.

Fix $x \in B(x_0, r)$. If f is nonnegative and vanishes in $B(x_0, q)$ and in $\mathfrak{X} \setminus V$, then (4.11) yields that

$$\pi_\psi f(x) = G_\psi(\psi f)(x) = \int_{V \setminus B(x,q)} G_\psi(x, y)\psi(y)f(y)m(dy).$$

Using (4.17) for $\hat{G}_\psi$ and the inequality $\varphi(y)\psi(y) \le \delta$ for $y \in V$, we have

$$\pi_\psi f(x) \le c_{(4.17)} \int_{V \setminus B(x,q)} \varphi(y)\psi(y)f(y)m(dy) \le c_{(4.17)}\delta \int_{V \setminus B(x,q)} f(y)m(dy), \tag{4.22}$$

with constant $c_{(4.17)}(x_0, r, p, q, R)$. Suppose now that $f \in \mathcal{D}(\mathcal{A})$ vanishes in V. By (4.12),

$$\begin{aligned}\pi_\psi f(x) = G_\psi \mathcal{A} f &= \int_V G_\psi(x, y) \left(\int_{\mathfrak{X} \setminus V} f(z)\nu(y, z)m(dz)\right) m(dy) \\ &= \int_{\mathfrak{X} \setminus V} \left(\int_V G_\psi(x, y)\nu(y, z)m(dy)\right) f(z)m(dz).\end{aligned}$$

We estimate the inner integral for $z \in \mathfrak{X} \setminus V$. Using (4.17) for $\hat{G}_\psi$, we have

$$\int_{V \setminus B(x_0,p)} G_\psi(x,y)\nu(y,z)m(dy) \le c_{(4.17)} \int_{V \setminus B(x_0,p)} \varphi(y)\nu(y,z)m(dy) = c_{(4.17)} \hat{\mathcal{A}}\varphi(z).$$

The integral over $B(x_0,p)$ is estimated as in the proof of Lemma 4.5,

$$\begin{aligned}\int_{B(x_0,p)} G_\psi(x,y)\nu(y,z)m(dy) &\le c_{(2.7)}\nu(x_0,z)\int_{B(x_0,p)} G_V(x,y)m(dy) \\ &\le c_{(2.7)}\nu(x_0,z)\mathbf{E}_x\tau_V \le c_{(2.7)}c_{(2.9)}\nu(x_0,z) \\ &\le \frac{c_{(2.9)}(c_{(2.7)})^2}{m(B(x_0,p))}\hat{\nu}(z,B(x_0,p)) \le c_{(4.17)}\hat{\mathcal{A}}\varphi(z),\end{aligned}$$

with constants $c_{(2.7)}(x_0,p,q)$, $c_{(2.9)}(x_0,R)$ and $c_{(4.17)}(x_0,r,p,q,R)$. Since $\hat{\mathcal{A}}\varphi(z) \le \delta$ and $\hat{\mathcal{A}}\varphi(z) \le \hat{\nu}(z,V)$, we obtain that

$$\pi_\psi f(x) \le 2c_{(4.17)} \int_{\mathfrak{X}\setminus V} f(z)\hat{\mathcal{A}}\varphi(z)m(dz) \le 2c_{(4.17)} \int_{\mathfrak{X}\setminus V} f(z)\min(\delta,\hat{\nu}(z,V))m(dz). \tag{4.23}$$

By approximation, (4.23) holds for any nonnegative f vanishing in $\overline{V}$. Formula (4.21) is a combination of (4.22), (4.23), $\pi_\psi(x,\partial V) = 0$ and $\pi_\psi(x,B(x_0,q)) = 0$ for all $x \in V$. ☐

Lemma 4.10. *If a nonnegative function f is regular subharmonic in $B(x_0,R)$, then $f(x) \le \pi_\psi f(x)$ for $x \in B(x_0,r)$. If f is regular harmonic, then equality holds.*

Proof. If f is regular subharmonic in V, then $f(x) \le \mathbf{E}_x(f(X(\tau_a)))$ for all $a \in [0,\infty]$ (see [18], Proposition II.2.8). If f is regular harmonic in V, then equality holds. The result follows by (4.9). ☐

The local maximum estimate is now proved as follows.

Proof of Theorem 3.4. Fix $p \in (r,q)$. Choose $\varepsilon > 0$ and φ as in the beginning of this section, and so that $\delta = \sup_{x\in\mathfrak{X}} \max(\mathcal{A}\varphi(x),\hat{\mathcal{A}}\varphi(x)) < \varrho(\overline{B}(x_0,q),B(x_0,R)) + \varepsilon$. Define ψ as in (4.20). By Lemmas 4.9 and 4.10, we have (3.7) with $\pi_{x_0,r,q,R}(y)$ bounded from above by $\pi_\psi(y)$ defined in (4.21). Note that $\hat{\nu}(y,V) \le \hat{\nu}(y,B(x_0,R))$. Since $\varepsilon > 0$ and $p \in (r,q)$ are arbitrary, formulas (3.8) and (3.9) follow. ☐

We conclude this section with a result on diffusion processes. The above argument remains valid when ν vanishes everywhere, i.e., X_t is a diffusion process. In this case (2.9) is not a consequence of Assumption C, so we need to add (2.9) as an assumption. No other changes in the argument are needed, and in fact the proof of Lemma 4.5 simplifies significantly, since X_t exits U through the boundary of U, and therefore $X(\tau_U)$ is never in $B(x_0,p)$. Therefore, we have proved the following result.

Theorem 4.11. *Assume that X_t is a diffusion process satisfying Assumptions A, B and D, and formula (2.9). Let $x_0 \in \mathfrak{X}$ and $0 < r < q < R < R_0$, where R_0 is the localization radius of 2.9 and Assumption D. Let f be a nonnegative function on $B(x_0,R)$, subharmonic in $B(x_0,R)$ with respect to X_t. Then*

$$f(x) \le c_{(4.24)} \int_{\overline{A}(x_0,q,R)} f(y)m(dy), \qquad x \in B(x_0,r). \tag{4.24}$$

Here $c_{(4.24)} = c_{(4.24)}(x_0,r,q,R) = c_{(2.10)}\delta$, where $\delta = \varrho(\overline{B}(x_0,q),B(x_0,R))$ and $c_{(2.10)} = c_{(2.10)}(x_0,r,q,R)$ are defined in Assumptions B and D.

Remark 4.12. For diffusion processes, local supremum estimate (4.24) for subharmonic functions is typically proved analytically, using Sobolev embeddings and Moser iteration, see, e.g., [41]. Theorem 3.4 requires more regularity of the process X_t as compared to the analytical approach because we assume the existence of bump functions in the domain of the Feller generator (Assumption B), while Moser iteration is based on the energy form. However, our approach does not depend on Sobolev embeddings, and so it applies also to Sierpiński carpets and some other highly irregular state spaces $\mathfrak{X}$. It would be interesting to find an analytical proof of the local supremum estimate for jump-type processes, which would not require Assumption B. Related results have been recently studied when the Lévy kernel $\nu(x, y)$ is comparable to $(d(x, y))^{-d-\alpha}$ (see [54] and the references therein). Further comments on this subject are given in Example 5.6 and Appendix A.

5. EXTENSIONS AND EXAMPLES

In this section we study several applications of our boundary Harnack inequality, and discuss limitations of Theorem 3.5. We sketch the range of possible applications by indicating rather general classes of processes satisfying the assumptions of Theorem 3.5, without getting into technical details. Before that, however, we discuss an important notion of scale-invariance introduced in Remark 3.6. This property can be proved in a fairly general setting, which we call *stable-like scaling.*

Definition 5.1. The process X_t is said to have *stable-like scaling* property with dimension $n > 0$, index $\alpha > 0$ and localization radius $R_0 \in (0, \infty]$ (α-stable-like scaling in short), if the following conditions are met:

(a) $\mathfrak{X}$ is locally an Ahlfors regular n-space; that is, $c^{-1} r^n \le m(B(x, r)) \le c r^n$ when $0 < r < R_0$ and $x \in \mathfrak{X}$;
(b) $c_{(2.7)}(x_0, r, R) \le c(r/R)$ when $0 < r < R < R_0$, $x_0 \in \mathfrak{X}$ in the relative constancy of the Lévy measure condition in Assumption C;
(c) $c_{(2.8)}(x_0, r, R) \ge c(r/R) R^{-n-\alpha}$ when $0 < r < R < R_0$, $x_0 \in \mathfrak{X}$, that is, $\nu(x, y) \ge c(d(x, y))^{-n-\alpha}$ when $d(x, y) < R_0$;
(d) $c_{(2.9)}(x_0, r) \le c r^\alpha$ when $0 < r < R_0$, $x_0 \in \mathfrak{X}$ in the upper bound for mean exit time from a ball;
(e) $c_{(2.10)}(x_0, r, p, R) \le c(r/R, p/R) R^{\alpha-n}$ when $0 < r < p < R < R_0$ and $x_0 \in \mathfrak{X}$ in the off-diagonal upper bound for the Green function of a ball;
(f) $\varrho(\overline{B}(x_0, r), B(x_0, R)) \le c(r/R) R^{-\alpha}$ when $0 < r < R < R_0$ and $x_0 \in \mathfrak{X}$, and $\varrho(\overline{A}(x_0, p, R), A(x_0, r, \tilde{r})) \le c(r/R, p/R, R/\tilde{r}) R^{-\alpha}$ when $0 < r < p < R < \tilde{r}$ in Assumption B.

Proposition 5.2. *If the scaling property (a) is satisfied, then conditions (b), (c) and (d) are consequences of:*

(g) *the Lévy kernel of X_t satisfies*

$$c^{-1} (d(x, y))^{-n-\alpha} \exp(-q d(x, y)) \le \nu(x, y) \le c(d(x, y))^{-n-\alpha} \exp(-q d(x, y))$$

for some $q \ge 0$ and for all $x, y \in \mathfrak{X}$.

Note that the same parameter q appears in the lower and the upper bound.

Proof. Conditions (b) and (c) follow directly from (g). Furthermore, by (a) and the triangle inequality, there is $R_0 > 0$ such that if $x_0 \in \mathfrak{X}$ and $0 < r < R_0$, then for some $y \in B(x_0, c_1 r) \setminus B(x_0, r)$ where $c_1 > 2$, the balls $B(x_0, r)$ and $B(y, r)$ are disjoint. Hence, for all $x \in B(x_0, r)$ we have by (a) and (g), $\nu(x, \mathfrak{X} \setminus B(x_0, r)) \ge \nu(x, B(y, r)) \ge c_2 r^{-\alpha}$.

As in the proof of Proposition 2.1, it follows that $\mathbf{P}_x(\tau_{B(x_0,r)} > t) \le \exp(-c_2 r^{-\alpha} t)$, and therefore $\mathbf{E}_x(\tau_{B(x_0,r)}) \le c_2^{-1} r^\alpha$. ☐

We also have the following sufficient condition for scaling properties (d) and (e).

Proposition 5.3. *Assume that scaling property (a) holds. Suppose that the transition density $T_t(x,y)$ of a Hunt process X_t exists, and that for some $\alpha > 0$, $r_0 > 0$,*

$$\frac{1}{c_{(5.1)}} \min\left(t^{-n/\alpha}, \frac{t}{(d(x,y))^{n+\alpha}}\right) \le T_t(x,y) \le c_{(5.1)} \min\left(t^{-n/\alpha}, \frac{t}{(d(x,y))^{n+\alpha}}\right) \tag{5.1}$$

for $x, y \in \mathfrak{X}$ with $d(x,y) < r_0$, and any $t \in (0, r_0^\alpha)$. Then Assumption D and scaling conditions (d) and (e) hold. The constant $c_{(2.10)}$ and the localization radius R_0 in (2.10) depend only on the constants in (5.1) (including α and r_0) and in the Ahlfors regularity condition.

Proof. Both cases $\alpha > n$ and $\alpha < n$ are very similar (in fact, slightly simpler) to the remaining case $\alpha = n$. Hence we give a detailed argument only when $\alpha = n$.

With no loss of generality we may assume that $r_0 < \operatorname{diam} X$. We choose $k > 2$ so that $m(B(x_0,kr) \setminus B(x_0,r)) \ge r^n$ for all $x_0 \in \mathfrak{X}$ and $r < r_0/k$. Let $r < r_0/(1+k)^{1+1/\alpha}$, $x_0 \in \mathfrak{X}$, $D = B(x_0,r)$, and let T_t^D be the transition kernel of the killed process X_t^D. Recall that $G_D(x,y) = \int_0^\infty T_t^D(x,y)dt$. Let $x, y \in D$ and let $t_1 = (d(x,y))^\alpha$, $t_2 = (2r)^\alpha$. Since $d(x,y) < 2r < r_0$, we have

$$\int_0^{t_1} T_t^D(x,y) \le \frac{c_{(5.1)}}{(d(x,y))^{n+\alpha}} \int_0^{t_1} t dt = \frac{c_{(5.1)}(d(x,y))^{\alpha-n}}{2},$$

and

$$\int_{t_1}^{t_2} T_t^D(x,y) \le c_{(5.1)} \int_{t_1}^{t_2} t^{-n/\alpha} dt = \alpha c_{(5.1)} \log \frac{2r}{d(x,y)}.$$

Note that for $\alpha > n$ or $\alpha < n$, we simply have a different expression for the above integral. When $t \in [t_2, 2t_2]$, we have $t < 2t_2 < 2^{1+\alpha} r^\alpha < r_0^\alpha$, and hence $T_t^D(x,y) \le c_{(5.1)} t_2{}^{-n/\alpha} = c_{(5.1)} (2r)^{-n}$. Furthermore, since $d(x,z) < (1+k)r < r_0$ for $z \in B(x_0,kr)$,

$$\begin{aligned}
T_{t_2}^D \mathbf{1}(x) &\le T_{t_2} \mathbf{1}_D(x) \le 1 - \int_{\mathfrak{X} \setminus D} T_{t_2}(x,z) m(dz) \\
&\le 1 - \frac{1}{c_{(5.1)}} \int_{B(x_0,kr) \setminus B(x_0,r)} \frac{t_2}{(d(x,z))^{n+\alpha}} m(dz) \\
&\le 1 - \frac{2^\alpha m(B(x_0,kr) \setminus B(x_0,r))}{c_{(5.1)} (k+1)^{n+\alpha} r^n} \le 1 - \frac{2^\alpha}{c_{(5.1)} (k+1)^{n+\alpha}}.
\end{aligned}$$

For $s = jt_2 + t$, $t \in [t_2, 2t_2]$, $j \ge 0$, we have $T_s^D = (T_{t_2}^D)^j T_t^D$. It follows that

$$T_s^D(x,y) \le \left(1 - \frac{2^\alpha}{c_{(5.1)} (k+1)^{n+\alpha}}\right)^j \frac{c_{(5.1)}}{(2r)^n},$$

and therefore, by summing up a geometric series,

$$\int_{t_2}^\infty T_t^D(x,y) dt \le 2^{-\alpha} (c_{(5.1)})^2 (k+1)^{n+\alpha} t_2 (2r)^{-n} = 2^{-n} (k+1)^{n+\alpha} (c_{(5.1)})^2 r^{\alpha-n}.$$

We conclude that $G_D(x,y) \le (c_{(5.1)}/2) + n c_{(5.1)} \log(2r/d(x,y)) + 2^{-n}(k+1)^{2n}(c_{(5.1)})^2$. This gives Assumption D and property (e). Property (d) follows by simple integration. ☐

If X_t has α-stable-like scaling, then, by a simple substitution, in Theorem 3.5 we have

$$\begin{aligned}
&c_{(3.9)}(x_0, r, q, R) \le c(r/R, q/R) R^{\alpha-d},\\
&c_{(3.11)}(x_0, q, R) \le c(q/R) R^{\alpha},\\
&c_{(1.1)}(x_0, r, R) \le c(r/R).
\end{aligned}$$

Hence the boundary Harnack inequality is uniform in all scales $R \in (0, R_0)$, or *scale-invariant*, as claimed in Remark 3.6. We state this result as a separate theorem for future reference.

Theorem 5.4. *If the assumptions of Theorem 3.5 are satisfied, and the process X_t has α-stable-like scaling, then the boundary Harnack inequality (BHI) is scale-invariant: $c_{(1.1)}(x_0, r, R)$ depends only on r/R.*

In typical applications, one verifies (typically quite straightforward) conditions (a) and (g), formula (5.1) (which has been proved for a fairly general class of processes), and condition (f). When dealing with processes given the Lévy kernel $\nu(x, y)$, condition (f) turns out to be the most restrictive one.

Example 5.5 (Lévy processes)**.** Theorem 3.5 applies to a large class of Lévy processes. In this case, the notion of processes in duality and properties of the Feller generator simplify significantly, see [70].

Let X_t be a Lévy process in $\mathfrak{X} = \mathbf{R}^k$ (with the Euclidean distance d and Lebesgue measure m). Then X_t is always Feller, and it is strong Feller if and only if the distribution of X_t is absolutely continuous (with respect to the Lebesgue measure). If this is the case, Assumption A is satisfied: the dual of X_t exists, and it is the reflected process, $\hat{X}_t - \hat{X}_0 = -(X_t - X_0)$. Assumption B is always satisfied with $\mathcal{D} = C_c^\infty(\mathbf{R}^k)$. The Lévy kernel of X_t is translation-invariant, $\nu(x, E) = \nu(E - x)$, where $\nu(dz)$ is the Lévy measure of X_t. Therefore, Assumption C can be restated as follows: the Lévy measure of X_t is absolutely continuous, and its density function $\nu(z)$ satisfies

$$c_{(2.7)}^{-1}\, \nu(z_0) \le \nu(z) \le c_{(2.7)}\, \nu(z_0), \qquad |z_0| > R,\ |z - z_0| < r, \tag{5.2}$$

whenever $0 < r < R$, with constant $c_{(2.7)}(0, r, R)$. If, e.g., $\nu(z)$ is isotropic and radially decreasing, then (5.2) is equivalent to $\nu(z_2) \ge c\nu(z_1)$ being valid whenever $|z_1| \ge 1$ and $|z_2| = |z_1| + 1$. Finally, Assumption D in many cases follows from estimates of the potential kernel $\mathcal{U}(x, y) = \mathcal{U}(y - x)$, or, in the recurrent case, the α-potential kernel $\mathcal{U}_\alpha(x, y) = \mathcal{U}_\alpha(y - x)$.

We conclude that boundary Harnack inequality holds for a Lévy process X_t, provided that its Lévy measure satisfies (5.2), one-dimensional distributions of X_t are absolutely continuous, and the Green functions of balls satisfy Assumption D. This class includes:

- subordinate Brownian motions which are not compound Poisson processes and have non-zero Lévy measure density function satisfying $\nu(z_2) \ge c\nu(z_1)$ if $|z_1| \ge 1$ and $|z_2| = |z_1| + 1$ (for properties of these processes, see, e.g., [23, 62]);
- (possibly asymmetric) Lévy processes with non-degenerate Brownian part and Lévy measure satisfying (5.2);
- (possibly asymmetric) strictly stable Lévy processes, whose Lévy measure is of the form $|z|^{-d-\alpha} f(z/|z|) dz$ for a function f bounded below and above by positive constants.

Scale-invariance is a different question, which depends on more accurate estimates. We list some examples.

- For the class of strictly stable Lévy processes described above, scale-invariance follows from the estimates of the transition density given in [79, Theorem 1.1] and Proposition 5.3; see also [28] and the references therein for related estimates in the symmetric (but anisotropic) case.
- Some Lévy processes for which Theorem 3.5 gives scale-invariant BHI are included in Example 5.6 (stable-like Lévy processes) and Example 5.8 (mixtures of isotropic stable processes, relativistic stable processes, etc.).
- A non-scale-invariant case (mixture of an isotropic stable process and the Brownian motion) is discussed in Example 5.13.
- Using the results of the first part of [63], one can obtain scale-invariant BHI for the class of Lévy processes considered therein (isotropic Lévy processes with Lévy measure comparable to the Lévy measure of a sufficiently regular subordinate Brownian motion), thus significantly simplifying the other part of that article.
- Also, the estimates given in [58], combined with Theorem 3.5, imply scale-invariant BHI at least for sufficiently regular subordinate Brownian motions (other than compound Poisson processes) with Lévy-Khintchine exponent slowly varying at ∞.

Example 5.6 (Stable-like processes)**.** Let $\mathfrak{X}$ be a closed set in $\mathbf{R}^k$, and let m be a measure on $\mathfrak{X}$ such that $\mathfrak{X}$, with the Euclidean distance, is an Ahlfors regular n-space for some $n > 0$. For example, $\mathfrak{X}$ can be entire $\mathbf{R}^k$ or the closure of an open set in $\mathbf{R}^k$ (with the Lebesgue measure m; then $n = k$). On the other hand, $\mathfrak{X}$ can be a fractal set, such as Sierpiński gaskets ($n = \log(k + 1)/\log 2$) or Sierpiński carpets ($n = \log(3^k - 1)/\log 3$) in $\mathbf{R}^2$, equipped with an appropriate Hausdorff measure. By this assumption, scaling property (a) is satisfied.

Let $\alpha \in (0, 2)$, and suppose that $\nu(x, y) = \nu(y, x)$ and

$$c_1|x - y|^{-n-\alpha} \le \nu(x, y) \le c_2|x - y|^{-n-\alpha}, \qquad x, y \in \mathfrak{X}. \tag{5.3}$$

This immediately gives Assumption C with scaling property (g).

By [33, Theorem 1], there is a Feller, strong Feller, symmetric pure-jump Hunt process X_t with Lévy kernel ν, and the continuous transition probability $T_t(x, y)$ of X_t satisfies (5.1) for some r_0. Assumption D and scaling property (e) follow by Proposition 5.3. Since X_t is symmetric (self-dual) and has continuous transition densities, Assumption A is also satisfied.

Finally, we assume that Assumption B holds with scaling property (f) (see below). Under the above assumptions, scale-invariant boundary Harnack inequality holds with some localization radius. When $\mathfrak{X}$ is unbounded, $\alpha \ne n$ and scaling property (a) holds for all $r > 0$, then (5.1) holds for all $t > 0$ and all $x, y \in \mathfrak{X}$, see [33], and therefore we can take $R_0 = \infty$.

We list some cases when Assumption B with scaling property (f) is known to hold true.

- When $\mathfrak{X} = \mathbf{R}^k$ and $\nu(x, y)$ is a function of $x - y$, then X_t is a symmetric Lévy process and we can simply take $\mathcal{D} = C_c^\infty(\mathbf{R}^k)$.
- More generally, let $\mathfrak{X} = \mathbf{R}^k$, and assume that $\nu(x, y) = \kappa(x, y)|y - x|^{-k-\alpha}$ for a $C_b^\infty(\mathbf{R}^k \times \mathbf{R}^k)$ function κ. We claim that Assumption B with scaling property (f) holds for $\mathcal{D} = C_c^\infty(\mathbf{R}^k)$. Indeed, for $f \in C_c^\infty(\mathbf{R}^k)$ let

$$\begin{aligned}\tilde{A}f(x) = \int_{\mathbf{R}^k} \left(f(x + z) - f(x) - \frac{z}{1 + |z|^2} \cdot \nabla f(x) \right) \frac{\kappa(x, x + z)}{|z|^{k+\alpha}} \, dz \\ + \left(\int_{\mathbf{R}^k} \frac{z}{1 + |z|^2} \, \frac{\kappa(x, x + z) - \kappa(x, x)}{|z|^{k+\alpha}} \, dz \right) \cdot \nabla f(x).\end{aligned} \tag{5.4}$$

Then $\tilde{A}$ is a symmetric pseudo-differential operator with appropriately smooth symbol, and by [48, Theorem 5.7], the closure of $\tilde{A}$ is the Feller generator of a symmetric Hunt process $\tilde{X}_t$ (we omit the details). Since the pure-jump Feller processes X_t and $\tilde{X}_t$ have equal Lévy kernels, they are in fact equal processes, and hence the closure of $\tilde{A}$ is the Feller generator of X_t. Assumption B with $\mathcal{D} = C_c^\infty(\mathbf{R}^k)$ follows, and scaling property (f) is a simple consequence of (5.4). See also [47, 77].

- When $\alpha \in (0,1)$, $\mathfrak{X}$ is the closure of an open Lipschitz set, and $\nu(x,y) = c|x-y|^{-k-\alpha}$, then the desired condition is satisfied by $\mathcal{D} = C_c^\infty(\mathbf{R}^k)$ (see [44, Theorem 6.1(i)]).
- When $\alpha \in [1,2)$, $\mathfrak{X}$ is the closure of an open set with $C^{1,\beta}$-smooth boundary for some $\beta > \alpha - 1$, and $\nu(x,y) = c|x-y|^{-k-\alpha}$, then one can take $\mathcal{D}$ to be the class of $C_c^\infty(\mathbf{R}^k)$ functions with normal derivative vanishing everywhere on the boundary of $\mathfrak{X}$ (see [44, Theorem 6.1(ii)]).
- For the case when X_t is a subordinate diffusion on $\mathfrak{X}$, see Example 5.7. In this case, when $\mathfrak{X}$ is a fractal set, one can even deal with α greater than 2.

Note that an analytical proof of Theorem 3.4 discussed in Remark 4.12 may lead to a generalization of this example, which would not require Assumption B.

Example 5.7 (Stable-like subordinate diffusions in metric measure spaces). Suppose that $(\mathfrak{X}, d, m)$ is an Ahlfors regular n-space for some $n > 0$. Assume that the metric d is uniformly equivalent to the shortest-path metric in $\mathfrak{X}$. Suppose that there is a diffusion process Z_t with a symmetric, continuous transition density $T_t^Z(x,y)$ satisfying the sub-Gaussian bounds

$$\begin{aligned} \frac{c_1}{t^{n/d_w}} \exp\left(-c_2 \left(\frac{d(x,y)^{d_w}}{t}\right)^{1/(d_w-1)}\right) &\le T_t^Z(x,y) \\ &\le \frac{c_3}{t^{n/d_w}} \exp\left(-c_4 \left(\frac{d(x,y)^{d_w}}{t}\right)^{1/(d_w-1)}\right) \end{aligned} \tag{5.5}$$

for all $x, y \in \mathfrak{X}$ and $t \in (0, t_0)$ ($t_0 = \infty$ when $\mathfrak{X}$ is unbounded). Here $d_w \ge 2$ is the *walk dimension* of the space $\mathfrak{X}$. The existence of such a diffusion process Z_t is well-known when $\mathfrak{X}$ is a Riemannian manifold ($d_w = 2$; see [42]), the k-dimensional Sierpiński gasket ($d_w = \log(k+3)/\log 2 > 2$; see [11]), more general nested fractals [40, 66], or the Sierpiński carpets [7, 8]; see [57] for more information.

Let $\alpha \in (0, d_w)$ and let X_t be the stable-like process obtained by subordination of Z_t with the α/d_w-stable subordinator η_t, $X_t = Z(\eta_t)$. These processes were first studied in [27, 67, 74]. By the subordination formula, the transition density estimate (5.1) holds for some r_0 (if $\mathfrak{X}$ is unbounded, then it was proved in [27] that we can take $r_0 = \infty$).

Since X_t is symmetric and has continuous transition densities, Assumption A is clearly satisfied. The Lévy kernel of X_t satisfies $c^{-1} d(x,y)^{-n-\alpha} \le \nu(x,y) \le c d(x,y)^{-n-\alpha}$, see [27], and Assumption C with scaling property (g) follows. Assumption D and scaling property (e) follow from the transition density estimate (5.1) by Proposition 5.3; see also [27, Lemmas 5.3 and 5.6]. Finally, Assumption B with scaling property (f) follows by the construction of [69, Section 2]. Roughly speaking, the method of [69] yields smooth bump functions in the domain of the generator of the diffusion Z_t with appropriate scaling. By the subordination formula, these bump functions are in the domain of $\mathcal{A}$, and the constants scale appropriately. Since there are some nontrivial issues related to the construction, we repeat the construction with all details in Appendix A. By Corollary A.4 there, Assumption B is satisfied with scaling property (f).

We conclude that scale-invariant boundary Harnack inequality for X_t holds in the full range of $\alpha \in (0, d_w)$. Noteworthy, we obtain a regularity result also for $\alpha \geq 2$, when Lipshitz functions no longer belong to the domain of the Dirichlet form of X_t.

This example can be extended in various directions. Instead of taking η_t the α/d_w-stable subordinator, one can consider a subordinator η_t whose Laplace exponent ψ is a complete Bernstein function regularly varying of order α/d_w ($\alpha \in (0, d_w)$) at infinity. Such subordinators have no drift, and the Lévy measure with completely monotone density function, regularly varying of order $-1-\alpha/d_w$ at 0. Their potential kernel is regularly varying of order $-1+\alpha/d_w$ at 0. We refer the reader to [23, 62, 71] for more information about subordination, complete Bernstein functions and regular variation. By the subordination formula, following the method applied for the Euclidean case $\mathfrak{X} = \mathbf{R}^k$ in [62, 63], one can obtain two-sided estimates for the Lévy kernel $\nu(x, y)$ and the potential kernel $\mathcal{U}(x, y)$ in terms of ψ, at least when $\mathfrak{X}$ is unbounded and $\alpha < d$. These estimates are sufficient to prove the scale-invariant boundary Harnack inequality.

Similar methods should be applicable also when X_t is recurrent (that is, $\mathfrak{X}$ is bounded, or $\alpha \geq d$). In this case, estimates of $\mathcal{U}(x, y)$ need to be replaced by estimates of the λ-potential kernel $\mathcal{U}_\lambda(x, y)$. Another interesting directions are the case of slowly varying ψ, which corresponds to $\alpha = 0$, and, on the other hand, the case of pure-jump processes with ψ regularly varying of order 1 (that is, $\alpha = d_w$). Finally, one can perturb processes considered above, in a similar way as in the next example.

Example 5.8 (Stability under small perturbations)**.** Let $\mathfrak{X} = \mathbf{R}^x$, d be the Euclidean distance, m be the Lebesgue measure, and $\alpha \in (0, 2)$. Suppose that $\tilde{\nu}(x, y)$ is a Lévy kernel of a Hunt process $\tilde{X}_t$ considered in Example 5.6, and $\tilde{A}$ is the corresponding Feller generator. For example, $\tilde{\nu}(x, y)$ can be any function of $y - x$ satisfying (5.3). In this example we consider a perturbation $\nu(x, y)$ of the kernel $\tilde{\nu}(x, y)$.

Although a more general construction is feasible, we are satisfied with the following setting. Let $\nu(x, y) = \tilde{\nu}(x, y) + n(x, y)$, where $n(x, y)$ is chosen so that $\nu(x, y)$ satisfies the scaling property (g), $n(x, y)$ and $\hat{n}(x, y) = n(y, x)$ are kernels of bounded operators on $C_0(\mathbf{R}^k)$, and

$$\int_{\mathbf{R}^k} n(x, y) dy = \int_{\mathbf{R}^k} \hat{n}(x, y) dy, \qquad\qquad x \in \mathbf{R}^k;$$

the last assumption guarantees that m is an excessive (in fact, invariant) measure for the process X_t defined below.

The formula $\mathcal{N} f(x) = \int_{\mathbf{R}^k} (f(y) - f(x)) n(x, y) dy$ defines a bounded linear operator on $C_0(\mathbf{R}^k)$, and $\mathcal{A} = \tilde{\mathcal{A}} + \mathcal{N}$ (defined on the domain of $\tilde{A}$) has the positive maximum property. By a standard perturbation argument, $\mathcal{A}$ is the Feller generator of a Hunt process X_t, and $\nu(x, y)$ is the Lévy kernel of X_t. The process $\hat{X}_t$ and its Feller generator $\hat{A}$ are constructed in a similar manner, using the Feller generator of the dual of $\tilde{X}_t$ and the kernel $\hat{n}(x, y)$. It is easy to see that $\int_{\mathbf{R}^k} \mathcal{A} f(x) g(x) dx = \int_{\mathbf{R}^k} f(x) \hat{\mathcal{A}} g(x) dx$ for $f, g \in C_c^\infty(\mathbf{R}^k)$, from which it follows that $\hat{X}_t$ is indeed the dual of X_t.

The transition density of $\tilde{X}_t$ satisfies (5.1) (see Example 5.6). The process X_t can be constructed probabilistically using $\tilde{X}_t$ and Meyer's method of adding and removing jumps. Hence, by [9, Lemma 3.6] and [10, Lemma 3.1(c)], the transition density of X_t exists and also satisfies (5.1) for smaller r_0 (see also [30, Proposition 2.1]).

It follows that Assumption A is satisfied. Assumption B holds with $\mathcal{D} = C_c^\infty(\mathbf{R}^k)$, and scaling property (f) (with finite R_0) follows from the α-stable-like scaling of $\tilde{A}$ and boundedness of $\mathcal{N}$. Since we assumed that (g) holds true, Assumption C is satisfied with scaling properties (b), (c). Assumption D and scaling properties (d), (e) follow from transition density estimate (5.1) by Proposition 5.3. Hence, scale-invariant boundary Harnack inequality holds true for X_t.

The above setting includes mixtures of isotropic stable processes (Lévy processes generated by $\mathcal{A} = -(-\Delta)^{\alpha/2} - c(-\Delta)^{\beta/2}$ with $0 < \beta < \alpha < 2$ and $c > 0$) and relativistic stable processes (Lévy processes generated by $\mathcal{A} = m - (-\Delta + m^{2/\alpha})^{\alpha/2}$ with $m > 0$). Also, the dependence of constants on the parameters c, β, m can be easily tracked. Since the perturbation $n(x, y)$ can be asymmetric, many non-symmetric processes are included. Finally, this example can be adapted to the setting of Ahlfors-regular n-sets in $\mathbf{R}^k$, as in Example 5.6.

Example 5.9 (Processes killed by a Schödinger potential)**.** Suppose that the assumptions for the boundary Harnack inequality in Theorem 3.5 are satisfied. Let $\mathfrak{X}'$ be an open set in $\mathfrak{X}$. Let M_t be a strong right-continuous multiplicative functional quasi-left continuous on $[0, \infty)$, for which all points of $\mathfrak{X}'$ are permanent, and such that $M_t = 0$ for $t \ge \tau_{\mathfrak{X}'}$. Finally, let X_t^M be the subprocess corresponding to M_t (in a similar way as in Section 4; see [18] for definitions). Then X_t^M is a Hunt process on $\mathfrak{X}'$, uniquely determined by the relation $\mathbf{P}_x^M(X_t^M \in E) = \mathbf{E}_x(M_t; X_t \in E)$ for any $E \subseteq \mathfrak{X}'$ and $x \in \mathfrak{X}'$.

Assume that M_t is a continuous function of $t \in [0, \tau_{\mathfrak{X}'})$. We claim that in this case the Lévy kernel $\nu^M(x, y)$ of X_t^M is again given by $\nu(x, y)$, restricted to $\mathfrak{X}' \times \mathfrak{X}'$. Indeed, by formula (4.6) of Lemma 4.3, for $x \in \mathfrak{X}'$ and $f \in \mathcal{D}(\mathcal{A})$ vanishing in a neighborhood of x, we have

$$\begin{aligned} \mathbf{E}_x^M(f(X_t^M)) - f(x) &= \mathbf{E}_x(f(X_t)M_t) - f(x) \\ &= \mathbf{E}_x\left(\int_0^t \mathcal{A}f(X_t)M_t dt\right) + \mathbf{E}_x\left(\int_0^t f(X_t) dM_t\right). \end{aligned}$$

When divided by t, this converges (for a fixed x) to $\mathcal{A}f(x)$ as $t \to 0^+$. Hence, $\nu^M f(x) = \nu f(x)$. By an approximation argument, this holds for any $f \in C_c(\mathfrak{X}')$ vanishing in a neighborhood of x, proving our claim. (Note that, however, in general, functions in $\mathcal{D}(\mathcal{A})$ need not belong to the domain of the generator of X_t^M, even if $\mathfrak{X}' = \mathfrak{X}$.)

We remark that many such functionals M_t are related to Schrödinger potentials V: for a nonnegative function V, we have $M_t = \exp(-\int_0^t V(X_s) ds)$ for $t < \tau_{\mathfrak{X}'}$, see [18]. A similar construction was used in Section 4 for a particular choice of V. In some applications, the potential V can take negative values, the case not covered by this example.

Let $D \subseteq \mathfrak{X}$ be an open set. By the definition of a subharmonic function, a nonnegative function f regular subharmonic on $D \cap \mathfrak{X}'$ with respect to the process X_t^M, extended by $f(x) = 0$ for $x \in \mathfrak{X} \setminus \mathfrak{X}'$, is also regular subharmonic in D with respect to X_t. Hence, the hypothesis of Theorem 3.4 holds for X_t^M with the same constant $c_{(3.9)}$. Of course, one needs to replace the sets in the statement of Theorem 3.4 by their intersections with $\mathfrak{X}'$.

We claim that also Lemma 3.1 holds for X_t^M with the same constant. Indeed, with the definitions of the proof of Lemma 3.1 and $D' = D \cap \mathfrak{X}'$, for $x \in B(x_0, r) \cap \mathfrak{X}'$ we have

$$\begin{aligned} \mathbf{P}_x^M(X_{\tau_{D'}}^M \in \mathfrak{X}' \setminus B(x_0, R)) &= \mathbf{E}_x(M_{\tau_D}; X_{\tau_D} \in \mathfrak{X} \setminus B(x_0, R)) \\ &\le \mathbf{E}_x(f(X_{\tau_D})M_{\tau_D}) - f(x). \end{aligned}$$

By formula (4.6) of Lemma 4.3,

$$\mathbf{E}_x(f(X_{\tau_D})M_{\tau_D}) - f(x) = \mathbf{E}_x\left(\int_0^{\tau_D} \mathcal{A}f(X_t)M_t dt\right) + \mathbf{E}_x\left(\int_{[0,\tau_D+]} f(X_t) dM_t\right).$$

The second summand on the right hand side is nonpositive. It follows that,

$$\begin{aligned}\mathbf{P}_x^M(X_{\tau_D}^M \in \mathfrak{X}' \setminus B(x_0,R)) &\le \mathbf{E}_x\left(\int_0^{\tau_D} M_t dt\right) \sup_{y\in\mathfrak{X}} \mathcal{A}f(y) \\ &= \mathbf{E}_x^M(\tau_{D'}) \sup_{y\in\mathfrak{X}} \mathcal{A}f(y),\end{aligned}$$

as desired.

In Lemma 3.2, only the estimates of the Lévy measure and mean exit time are used. Therefore, also Lemma 3.2 holds for the process X_t^M with unaltered constants. In a similar way, the proof of Theorem 3.5 works for the process X_t^M without modifications. We conclude that the boundary Harnack inequality holds for X_t^M with the same constants. For convenience, we state this result as a separate theorem.

Theorem 5.10. *Suppose that Assumptions A, B, C and D hold true. Let $\mathfrak{X}'$ be an open subset of $\mathfrak{X}$, and let X_t^M be a subprocess of X_t, with state space $\mathfrak{X}'$, corresponding to a strong right-continuous multiplicative functional for X_t, continuous before X_t hits $\mathfrak{X} \setminus \mathfrak{X}'$, vanishing after that time, and quasi-left continuous on* $[0,\infty)$. *Then the boundary Harnack inequality holds true for the process X_t^M with the same constant $c_{(1.1)}$ given by* (3.10). *More precisely, if $x_0 \in \mathfrak{X}$, $0 < r < R < R_0$, $D \subseteq B(x_0,R)$ is open, f, g are nonnegative regular harmonic functions in $D \cap \mathfrak{X}'$ (with respect to the process X_t^M), and f, g vanish in $(B(x_0,R) \setminus D) \cap \mathfrak{X}'$, then we have*

$$f(x)g(y) \le c_{(1.1)}\, g(x)f(y)\,, \qquad\qquad x, y \in B(x_0,r) \cap D \cap \mathfrak{X}',$$

where $c_{(1.1)} = c_{(1.1)}(x_0,r,R)$ does not depend on M_t.

We remark that the continuity assumption for M_t is essential. If, for example, M_t is equal to 1 until the first jump larger than 1, and then 0, the boundary Harnack inequality typically does not hold, by an argument similar to one in Example 5.14 below.

Example 5.11 (Actively reflected and censored stable processes)**.** Let $\mathfrak{X}' \subseteq \mathbf{R}^k$ be open and let $\mathfrak{X}$ be the closure of $\mathfrak{X}'$ in $\mathbf{R}^k$. Suppose that $\mathfrak{X}$ satisfies property (a). Let $\nu(x,y) = c|x-y|^{-n-\alpha}$. As in Example 5.6, under suitable assumptions on $\mathfrak{X}$, there is a stable-like process X_t with the Lévy kernel $\nu(x,y)$, and scale-invariant BHI holds for X_t. In [21], the process X_t is called actively reflected α-stable process in $\mathfrak{X}$, and the process X_t', obtained from X_t by killing it upon hitting $\mathfrak{X} \setminus \mathfrak{X}'$, is named censored α-stable process in $\mathfrak{X}'$ (see [21, Remark 2.1]). Clearly, the boundary Harnack inequality for X_t' is the special case of the boundary Harnack inequality for X_t, corresponding to open sets D contained in $\mathfrak{X}'$. (Note that this is in fact a special case of Theorem 5.10, with $M_t = 1$ for $t < \tau_{\mathfrak{X}'}$.) Hence, we have scale-invariant BHI for the actively reflected α-stable process X_t and the censored α-stable process X_t', whenever $\mathfrak{X}'$ is a Lipschitz set in the case $\alpha \in (0,1)$, and $\mathfrak{X}'$ is an open set with $C^{1,\beta}$-smooth boundary for some $\beta > \alpha - 1$ in the case $\alpha \in [1,2)$. The above extends the results of [21, 43].

Example 5.12 (Gradient-type perturbations of stable processes)**.** Let $\alpha \in (1,2)$. If $b : \mathbf{R}^k \to \mathbf{R}^k$ is bounded and differentiable, partial derivatives of b are bounded, and $\operatorname{div} b = 0$, then the process X_t generated by $-(-\Delta)^{\alpha/2} + b \cdot \nabla$, and the process $\hat{X}_t$ generated by $-(-\Delta)^{\alpha/2} - b \cdot \nabla$ are mutually dual. Such processes are considered in the recent paper [51]. The Lévy kernels of X_t and $\hat{X}_t$ are the same as that of the isotropic

α-stable Lévy process generated by $(-\Delta)^{\alpha/2}$, see [25]. Furthermore, $\mathcal{D} = C_c^\infty(\mathbf{R}^k)$ is contained in the domains of $\mathcal{A}$ and $\hat{\mathcal{A}}$. Therefore, a scale-invariant (with finite R_0) boundary Harnack inequality holds for the process X_t.

We conclude this article with some negative or partially negative examples.

Example 5.13 (Lévy processes with Brownian component)**.** Let $\mathfrak{X} = \mathbf{R}^k$, d be the Euclidean distance, m be the Lebesgue measure, and $\alpha \in (0, 2)$. Let X_t be the sum of two independent processes, the Brownian motion and the isotropic α-stable Lévy process. That is, X_t is the Lévy process with generator $\mathcal{A} = c_1\Delta - c_2(-\Delta)^{\alpha/2}$.

Clearly, X_t is symmetric and has transition densities, so Assumption A is satisfied. Furthermore, $\mathcal{D}(\mathcal{A})$ contains $C_c^\infty(\mathbf{R}^k)$, and hence Assumption B is satisfied with 2-stable-like scaling: the property (f) holds with α replaced by 2. On the other hand, Assumption C clearly holds with α-stable-like scaling (g). Furthermore, detailed estimates for the transition density of X_t can be established ([34]), from which Assumption D follows as in Proposition 5.3, with 2-stable scaling.

It follows that boundary Harnack inequality holds despite the diffusion component. However, the constant $c_{(1.1)}(x_0, r, R)$ is not bounded when, for example, $R = 2r$ and $r \to 0^+$. This is a typical behavior for processes comprising both jump and diffusion part, and for general open sets one cannot expect a scale-invariant result: the boundary Harnack inequality in the form given in (BHI) does not hold for the Brownian motion without some regularity assumptions on the boundary of D, cf. [14]. On the other hand, the scale-invariant boundary Harnack inequality for X_t in more smooth domains was established in [32].

Example 5.14 (Truncated stable processes)**.** This example shows why Assumption C is essential for the boundary Harnack inequality in the form given in (BHI). Consider the truncated isotropic α-stable Lévy process X_t in $\mathfrak{X} = \mathbf{R}^k$, $\alpha \in (0, 2)$, $n \geq 1$. This is a pure-jump Lévy process with Lévy kernel $\nu(x, y) = c|x - y|^{-n-\alpha}\mathbf{1}_{B(x,1)}(y)$. Clearly, Assumptions A, B and D, as well as formula (2.9), hold true with α-stable-like scaling and $R_0 = 1$, but Assumption C is violated.

We examine two specific harmonic functions. Let v be a vector in $\mathbf{R}^d$ with $|v| = 2/3$, let $r \in (0, 1/6)$ be a small number, and define $B_1 = B(x_1, r)$ and $B_2 = B(x_2, r)$, where $x_1, x_2 \in \mathbf{R}^k$ are arbitrary points satisfying $x_1 - x_2 = v$. Let $D = B_1 \cup B_2$, $E_1 = B_1 + v$, $E_2 = B_2 - v$, and let $f_j(x) = \mathbf{P}_x(X(\tau_D) \in E_j)$. Suppose that $x \in B_1$. By (2.12), we have

$$3^{-n-\alpha}c|E_1|\mathbf{E}_x\tau_{B_1} \leq f_1(x) \leq 3^{n+\alpha}c|E_1|\mathbf{E}_x\tau_D.$$

When $x \in B_2$, then, again by (2.12),

$$\begin{aligned} f_1(x) &\leq \mathbf{P}_x(X(\tau_{B_2}) \in B_1) \cdot \sup_{y \in B_1} f_1(y) \\ &\leq c3^{n+\alpha}|B_1|\mathbf{E}_x\tau_{B_2} \cdot 3^{n+\alpha}c|E_1| \sup_{y \in B_2} \mathbf{E}_y\tau_D. \end{aligned}$$

Similar estimates hold true for f_2. It follows that

$$\begin{aligned} \frac{f_1(x_2)f_2(x_1)}{f_1(x_1)f_2(x_2)} &\leq c_{n,\alpha}^2(3^{n+\alpha})^6|B_1|\,|B_2|\left(\sup_{y \in D}\mathbf{E}_y\tau_D\right)^2 \\ &\leq c_{n,\alpha}^2(3^{n+\alpha})^6|B(0,1)|^2r^{2n}\left(\sup_{y \in B(0,1)}\mathbf{E}_y\tau_{B(0,1)}\right)^2. \end{aligned}$$

This ratio can be arbitrarily small when $r \to 0$, and therefore (BHI) cannot hold for truncated stable process uniformly with respect to the domain. We remark that by an appropriate modification of the above example, one can even construct a single domain (an infinite union of balls) for which (BHI) is false. Also, modifications of the above example for other truncated processes, or for processes with super-exponential decay of the density of the Lévy measure can be given.

On the other hand, if the regular harmonic functions f and g (of the truncated α-stable process X_t) vanish outside a unit ball, then clearly f and g are harmonic in D also with respect to the standard (that is, non-truncated) isotropic α-stable process in $\mathbf{R}^k$. Therefore, the boundary Harnack inequality actually holds true for such functions. A different version of boundary Harnack inequality was proved for X_t under some regularity assumptions on the domain of harmonicity in [59, 60].

APPENDIX A. SMOOTH BUMP FUNCTIONS ON METRIC MEASURE SPACES WITH SUB-GAUSSIAN HEAT KERNELS

In this part we repeat the construction of smooth bump functions of [69]. We adopt the setting of Example 5.7: Z_t is a diffusion process on an Ahlfors-regular n-space $\mathfrak{X}$, the transition semigroup T_t^Z of Z_t satisfies sub-Gaussian bounds (5.5), and X_t is defined to be the process Z_t subordinated by an independent α/d_w-stable subordinator, $\alpha \in (0, d_w)$. The generator of Z_t serves as the (Neumann) Laplacian Δ on $\mathfrak{X}$, and T_t^Z is the heat semigroup.

Let $h = T_t^Z g$ for some $t > 0$ and $g \in L^2(\mathfrak{X})$. One of the main results of [69], Theorem 2.2, states that given any compact K and $\varepsilon > 0$, there is a function f such that $f \in \mathcal{D}(\Delta^l)$ for all $l > 0$, $f(x) = h(x)$ on K and $f(x) = 0$ when $\operatorname{dist}(x, K) \geq \varepsilon$. There are at least three issues when one tries to apply this result in our setting.

First, Theorem 2.2 in [69] is given under the assumption that the spectral gap of Δ is positive. However, this assumption is used only in the proof of Lemma 2.6, which contains a flaw: positivity of the spectral gap λ does not imply the inequality $\|P_t f - f\|_{L^2(\mathfrak{X})} \leq \lambda t \|f\|_{L^2(\mathfrak{X})}$ (see line 3 on page 1769 and line 12 on page 1773 in [69]). This issue has been resolved by the authors of [69] in an unpublished note, containing a corrected version of the proof of Lemma 2.6. The new argument does not involve the condition on the spectral gap, which therefore turns out to be superfluous. For future reference, we provide the corrected version of the proof of Lemma 2.6 below.

Second, to get Assumption B, we need to apply the above theorem with $h(x) = 1$ for $x \in K$, where $h = T_t^Z g$. This condition is satisfied when $g(x) = 1$ for all $x \in \mathfrak{X}$. However, such a function g is in $L^2(\mathfrak{X})$ only when m is a finite measure, and the general case is not covered by [69]. For that reason, we choose to repeat the construction of [69] in $L^\infty(\mathfrak{X})$ (instead of $L^2(\mathfrak{X})$) setting.

Finally, for a scale-invariant boundary Harnack inequality, we need an upper bound for $\|\Delta f\|_{L^\infty(\mathfrak{X})}$ with explicit dependence on scale, that is, explicit in ε and the size (e.g. the diameter) of K. Such properties of the estimates are irrelevant in [69], but it turns out that they can be obtained by carefully following the proof of Theorem 2.2 in [69].

For the above reasons, we decide to give a complete proof of an $L^\infty(\mathfrak{X})$ version of Theorem 2.2 in [69]. However, it should be emphasized that method was completely developed in [69]. Although we only need the result for $g(x) = h(x) = 1$ for all $x \in \mathfrak{X}$, for future reference we consider the general case.

Theorem A.1 (a variant of [69, Theorem 2.2]). *Suppose that $K \subseteq \mathfrak{X}$ is a compact set, $\varepsilon, s > 0$ and $h = T_s^Z g$ for some $g \in L^\infty(\mathfrak{X})$. Then there is a function $f \in L^\infty(\mathfrak{X})$ such that $f(x) = h(x)$ for $x \in K$, $f(x) = 0$ when $\operatorname{dist}(x, K) \geq \varepsilon$, and $f \in \mathcal{D}(\Delta^l)$ for any $l > 0$. Furthermore, the $L^\infty(\mathfrak{X})$ norm of f is bounded by the $L^\infty(\mathfrak{X})$ norm of g, f is nonnegative* *if g is nonnegative, and for all $l > 0$ we have*

$$\left\|\Delta^l f\right\|_{L^\infty(\mathfrak{X})} \le \frac{c_{(A.1)}(\operatorname{diam} K + \varepsilon)^{n/2}}{\varepsilon^{l d_w + n/2}} \left\|g\right\|_{L^\infty(\mathfrak{X})} , \tag{A.1}$$

where $c_{(A.1)} = c_{(A.1)}(l, \varepsilon^{d_w}/s, Z_t)$.

Proof. We divide the argument into five steps. All constants in this proof may depend not only on the parameters given in parentheses, but also on the space $\mathfrak{X}$ and the process Z_t. Since we never refer to the semigroup of the subordinate process X_t, in this proof for simplicity we write $T_t = T_t^Z$. Furthermore, also in this proof only, we extend Δ to the $L^\infty(\mathfrak{X})$ generator of T_t (recall that originally Δ was defined as the $C_0(\mathfrak{X})$ generator), and denote by $\Delta_{L^2(\mathfrak{X})}$ the $L^2(\mathfrak{X})$ generator of T_t, that is, the generator of the semigroup of operators T_t acting on $L^2(\mathfrak{X})$. Clearly, $\Delta f = \Delta_{L^2(\mathfrak{X})} f$ m-a.e. whenever $f \in \mathcal{D}(\Delta) \cap \mathcal{D}(\Delta_{L^2(\mathfrak{X})})$.

Step 1. We begin with some general estimates. By the spectral theorem and the inequality $\lambda^l e^{-\lambda t} \le (le/t)^l$, for any $f \in L^2(\mathfrak{X})$ and $l \ge 0$, we have $T_t f \in \mathcal{D}((\Delta_{L^2(\mathfrak{X})})^l)$, and

$$\left\|(\Delta_{L^2(\mathfrak{X})})^l T_t f\right\|_{L^2(\mathfrak{X})} \le (le/t)^l \left\|f\right\|_{L^2(\mathfrak{X})} .$$

Furthermore, by sub-Gaussian estimates (5.5), $\|T_t(x, \cdot)\|_{L^2(\mathfrak{X})} = (T_{2t}(x,x))^{1/2} \le c_1 t^{-n/(2d_w)}$. Hence,

$$\left\|T_t f\right\|_{L^\infty(\mathfrak{X})} \le c_1 t^{-n/(2d_w)} \left\|f\right\|_{L^2(\mathfrak{X})} .$$

We find that

$$\left\|\frac{T_s T_t f - T_t f}{s} - \Delta_{L^2(\mathfrak{X})} T_t f\right\|_{L^\infty(\mathfrak{X})} \le \frac{c_1}{(t/2)^{n/(2d_w)}} \left\|\frac{T_s T_{t/2} f - T_{t/2} f}{s} - \Delta_{L^2(\mathfrak{X})} T_{t/2} f\right\|_{L^2(\mathfrak{X})} \to 0$$

as $s \to 0^+$. It follows that $T_t f \in \mathcal{D}(\Delta)$, with $\Delta T_t f = \Delta_{L^2(\mathfrak{X})} T_t f$. By a similar argument, $T_t f \in \mathcal{D}(\Delta^l)$ for any $l \ge 0$, and

$$\left\|\Delta^l T_t f\right\|_{L^\infty(\mathfrak{X})} = \left\|T_{t/2} \Delta^l T_{t/2} f\right\|_{L^\infty(\mathfrak{X})} \le \frac{c_2}{t^{n/(2d_w)}} \left\|\Delta^l T_{t/2} f\right\|_{L^2(\mathfrak{X})} \le \frac{c_3(l)}{t^{l + n/(2d_w)}} \left\|f\right\|_{L^2(\mathfrak{X})} .$$

Sub-Gaussian estimate (5.5) and Ahlfors regularity of $\mathfrak{X}$ also give the following estimate: for any set $E \subseteq \mathfrak{X}$, any $\varepsilon > 0$ and any $f \in L^\infty(\mathfrak{X})$ or $f \in L^1(\mathfrak{X})$ vanishing in the ε-neighborhood of E, we have

$$\left\|T_t f\right\|_{L^\infty(E)} \le D(\varepsilon, t) \left\|f\right\|_{L^\infty(\mathfrak{X})} , \qquad \text{and} \qquad \left\|T_t f\right\|_{L^1(E)} \le D(\varepsilon, t) \left\|f\right\|_{L^1(\mathfrak{X})} ,$$

where

$$D(\varepsilon, t) = \sup_{x \in \mathfrak{X}} \int_{\mathfrak{X} \setminus B(x, \varepsilon)} T_t(x, y) m(dy) \le c_4 \exp(-c_5 (\varepsilon^{d_w}/t)^{1/(d_w - 1)}).$$

In particular, given any $s > 0$ and $\varepsilon > 0$ it is possible to choose a strictly increasing sequence $s_j > 0$ convergent to s, with $s_0 = 0$, such that if $t_j = s_j - s_{j-1}$ ($j \ge 1$), then

$$\lim_{j \to \infty} D(2^{-j}\varepsilon, s - s_j) = 0 \qquad \text{and} \qquad \sum_{i=1}^{\infty} \frac{D(2^{-i}\varepsilon, t_i)}{t_{i+1}^l} \le \frac{c_6(l, \varepsilon^{d_w}/s)}{\varepsilon^{l d_w}} < \infty$$

for any $\varepsilon > 0$, $l \ge 0$. For example, one can take $s_j = (1 - 4^{-d_w j})s$. Note, however, that the above series would diverge if t_j decreased either too slowly or too rapidly.

Step 2. Let $g \in L^\infty(\mathfrak{X})$, $\varepsilon, s > 0$, and $h(x) = T_s g(x)$, as in the statement of the theorem. Following [69], for $j \ge 0$ we define

$$K_j = \{x \in \mathfrak{X} : \operatorname{dist}(x, K) < 2^{-j}\varepsilon\}, \qquad L_j = \{x \in \mathfrak{X} : \operatorname{dist}(x, K) > (1 - 2^{-j})\varepsilon\},$$

and $A_j = \mathfrak{X} \setminus (K_j \cup L_j)$. Furthermore, let s_j and t_j be chosen as in Step 1. For $j \ge 1$ we define

$$u_0(x) = 0, \qquad\qquad u_j(x) = \mathbf{1}_{K_j}(x) T_{s_j} g(x) + \mathbf{1}_{A_j}(x) T_{t_j} u_{j-1}(x).$$

Below we prove that $T_{s-s_j} u_j$ converges to a function f with the desired properties.

Step 3. By induction, $\|u_j\|_{L^\infty(\mathfrak{X})} \le \|g\|_{L^\infty(\mathfrak{X})}$ for any $j \ge 0$. For $j \ge 1$ we have $u_{j-1}(x) = T_{s_{j-1}} g(x)$ for $x \in K_{j-1}$, and $\operatorname{dist}(K_j, \mathfrak{X} \setminus K_{j-1}) \ge 2^{-j}\varepsilon$. Hence,

$$\begin{aligned} \left\|u_j - T_{t_j} u_{j-1}\right\|_{L^\infty(K_j)} &= \left\|T_{t_j}(T_{s_{j-1}} g - u_{j-1})\right\|_{L^\infty(K_j)} \\ &\le D(2^{-j}\varepsilon, t_j) \left\|T_{s_{j-1}} g - u_{j-1}\right\|_{L^\infty(\mathfrak{X})} \le 2D(2^{-j}\varepsilon, t_j) \left\|g\right\|_{L^\infty(\mathfrak{X})} , \end{aligned} \tag{A.2}$$

where $D(2^{-j}\varepsilon, t_j)$ is as in Step 1 (cf. [69, Lemma 2.3]). Also, u_j vanishes on L_j, u_{j-1} vanishes on L_{j-1}, and $\operatorname{dist}(L_j, \mathfrak{X} \setminus L_{j-1}) \ge 2^{-j}\varepsilon$, so that

$$\left\|u_j - T_{t_j} u_{j-1}\right\|_{L^\infty(L_j)} = \left\|T_{t_j} u_{j-1}\right\|_{L^\infty(L_j)} \le D(2^{-j}\varepsilon, t_j) \left\|u_{j-1}\right\|_{L^\infty(\mathfrak{X})} ,$$

and (using $\mathfrak{X} \setminus L_{j-1} \subseteq K_0$)

$$\begin{aligned} \left\|u_j - T_{t_j} u_{j-1}\right\|_{L^1(L_j)} &= \left\|T_{t_j} u_{j-1}\right\|_{L^1(L_j)} \\ &\le D(2^{-j}\varepsilon, t_j) \left\|u_{j-1}\right\|_{L^1(\mathfrak{X})} \le D(2^{-j}\varepsilon, t_j) m(K_0) \left\|u_{j-1}\right\|_{L^\infty(\mathfrak{X})} . \end{aligned}$$

Hence, using also $\|u_{j-1}\|_{L^\infty(\mathfrak{X})} \le \|g\|_{L^\infty(\mathfrak{X})}$, we obtain (cf. [69, Lemma 2.5])

$$\begin{aligned} \left\|u_j - T_{t_j} u_{j-1}\right\|_{L^2(L_j)} &\le \sqrt{\left\|u_j - T_{t_j} u_{j-1}\right\|_{L^\infty(L_j)} \left\|u_j - T_{t_j} u_{j-1}\right\|_{L^1(L_j)}} \\ &\le D(2^{-j}\varepsilon, t_j) \sqrt{m(K_0)} \left\|g\right\|_{L^\infty(\mathfrak{X})} . \end{aligned} \tag{A.3}$$

Step 4. We follow the corrected version of the proof of [69, Lemma 2.6]. Let $l \ge 0$. For $j \ge 1$ we have

$$\Delta^l T_{s-s_j} u_j = \sum_{i=1}^{j} \Delta^l T_{s-s_i}(u_i - T_{t_i} u_{i-1}).$$

Observe that the results of Step 1 and the equality $u_i(x) = T_{t_i} u_{i-1}(x)$ for $x \in A_i$ give

$$\begin{aligned} \sum_{i=1}^{\infty} \left\|\Delta^l T_{s-s_i}(u_i - T_{t_i} u_{i-1})\right\|_{L^\infty(\mathfrak{X})} &\le \sum_{i=1}^{\infty} \frac{c_3(l)}{(s - s_i)^{l+n/(2d_w)}} \left\|u_i - T_{t_i} u_{i-1}\right\|_{L^2(\mathfrak{X})} \\ &\le \sum_{i=1}^{\infty} \frac{c_3(l)}{t_{i+1}^{l+n/(2d_w)}} \Bigl(\left\|u_i - T_{t_i} u_{i-1}\right\|_{L^2(K_i)} + \left\|u_i - T_{t_i} u_{i-1}\right\|_{L^2(L_i)} \Bigr) . \end{aligned}$$

Hence, by (A.2) and (A.3),

$$\begin{aligned} \sum_{i=1}^{\infty} \left\|\Delta^l T_{s-s_i}(u_i - T_{t_i} u_{i-1})\right\|_{L^\infty(\mathfrak{X})} &\le 3c_3(l) \sqrt{m(K_0)} \left\|g\right\|_{L^\infty(\mathfrak{X})} \sum_{i=1}^{\infty} \frac{D(2^{-i}\varepsilon, t_i)}{t_{i+1}^{l+n/(2d_w)}} \\ &\le 3c_3(l) \sqrt{m(K_0)} \left\|g\right\|_{L^\infty(\mathfrak{X})} \frac{c_6(l + n/(2d_w), \varepsilon^{d_w}/s)}{\varepsilon^{l d_w + n/2}} . \end{aligned}$$

It follows that the sequence $\Delta^l T_{s-s_j} u_j$ converges in $L^\infty(\mathfrak{X})$ as $j \to \infty$ for every $l \geq 0$. Therefore, if $f(x) = \lim_{j\to\infty} T_{s-s_j} u_j(x)$, then for all $l \geq 0$ we have $f \in \mathcal{D}(\Delta^l)$ and

$$\begin{aligned}\left\|\Delta^l f\right\|_{L^\infty(\mathfrak{X})} &\leq \sum_{i=1}^{\infty} \left\|\Delta^l T_{s-s_i}(u_i - T_{t_i} u_{i-1})\right\|_{L^\infty(\mathfrak{X})} \\ &\leq \frac{c_7(l, \varepsilon^{d_w}/s)}{\varepsilon^{l d_w + n/2}} \sqrt{m(K_0)}\, \|g\|_{L^\infty(\mathfrak{X})} ,\end{aligned}$$

as desired.

Step 5. By the definition of u_j, for $j \geq 1$ we have

$$\begin{aligned}T_{s-s_j} u_j &= T_{s-s_j}(\mathbf{1}_{K_j} T_{s_j} g + \mathbf{1}_{A_j} T_{t_j} u_{j-1}) \\ &= T_s g + T_{s-s_j}(\mathbf{1}_{A_j} T_{t_j} u_{j-1} - \mathbf{1}_{\mathfrak{X}\setminus K_j} T_{s_j} g).\end{aligned}$$

It follows that

$$\begin{aligned}\left\|T_{s-s_j} u_j - T_s g\right\|_{L^\infty(K)} &= \left\|T_{s-s_j}(\mathbf{1}_{A_j} T_{t_j} u_{j-1} - \mathbf{1}_{\mathfrak{X}\setminus K_j} T_{s_j} g)\right\|_{L^\infty(K)} \\ &\leq D(2^{-j}\varepsilon, s - s_j) \left\|\mathbf{1}_{A_j} T_{t_j} u_{j-1} - \mathbf{1}_{\mathfrak{X}\setminus K_j} T_{s_j} g\right\|_{L^\infty(\mathfrak{X})} \\ &\leq 2D(2^{-j}\varepsilon, s - s_j) \|g\|_{L^\infty(\mathfrak{X})} .\end{aligned}$$

The right hand side converges to 0 as $j \to \infty$. Hence, $f(x) = T_s g(x) = h(x)$ for $x \in K$. Furthermore, $\|u_j\|_{L^\infty(\mathfrak{X})} \leq \|g\|_{L^\infty(\mathfrak{X})}$, and therefore also $\|f\|_{L^\infty(\mathfrak{X})} \leq \|g\|_{L^\infty(\mathfrak{X})}$. Finally, if $g \geq 0$, then $u_j \geq 0$ for all $j \geq 1$, and so $f \geq 0$. □

By choosing $g(x) = h(x) = 1$ and $s = \varepsilon^{d_w}$, we obtain the following result.

Corollary A.2. *Suppose that $K \subseteq \mathfrak{X}$ is a compact set and $\varepsilon > 0$. Then there is a function $f \in L^\infty(\mathfrak{X})$ such that $f(x) = 1$ for $x \in K$, $f(x) = 0$ when $\operatorname{dist}(x, K) \geq \varepsilon$, and $f \in \mathcal{D}(\Delta^l)$ for any $l > 0$. Furthermore, $0 \leq f(x) \leq 1$ for all $x \in \mathfrak{X}$, and for all $l > 0$ we have*

$$\left\|\Delta^l f\right\|_{L^\infty(\mathfrak{X})} \leq \frac{c_{(A.4)} (\operatorname{diam} K + \varepsilon)^{n/2}}{\varepsilon^{l d_w + n/2}} , \tag{A.4}$$

where $c_{(A.4)} = c_{(A.4)}(l, Z_t)$. □

In general, the boundary of the set $\{x \in \mathfrak{X} : f(x) > 0\}$ might be highly irregular. However, when we relax the smoothness hypothesis on f, we can require f to be positive on an arbitrary given open set.

Proposition A.3. *Suppose that $K \subseteq \mathfrak{X}$ is a compact set, $\varepsilon > 0$ and $L > 0$. Then there is a function $f \in L^\infty(\mathfrak{X})$ such that $f(x) = 1$ for $x \in K$, $f(x) = 0$ when $\operatorname{dist}(x, K) \geq \varepsilon$, and $f \in \mathcal{D}(\Delta^l)$ for $l = 1, 2, \ldots, L$. Furthermore, $0 \leq f(x) \leq 1$ for all $x \in \mathfrak{X}$, the boundary of the set $\{x \in \mathfrak{X} : f(x) > 0\}$ has zero m measure, and for all $l = 1, 2, \ldots, L$ we have*

$$\left\|\Delta^l f\right\|_{L^\infty(\mathfrak{X})} \leq \frac{c_{(A.5)} (\operatorname{diam} K + \varepsilon)^{n/2}}{\varepsilon^{l d_w + n/2}} , \tag{A.5}$$

where $c_{(A.5)} = c_{(A.5)}(L, Z_t)$.

Proof. Let f_0 be the function constructed in Theorem A.1 for $h(x) = g(x) = 1$, and denote by V an arbitrary open set with the following properties: $\{x \in \mathfrak{X} : f(x) > 0\} \subseteq V \subseteq \{x \in \mathfrak{X} : \operatorname{dist}(x, K) < 2\varepsilon\}$, and $m(\partial V) = 0$. For example, one can take $V = \{x \in \mathfrak{X} : \operatorname{dist}(x, K) < r\}$ for a suitable $r \in (\varepsilon, 2\varepsilon)$.

Let B_j, $j = 1, 2, \ldots$, be a family of balls contained in $V \cap \{x \in \mathfrak{X} : f_0(x) < 1/2\}$ such that twice smaller balls B'_j form a countable covering of $V \cap \{x \in \mathfrak{X} : f_0(x) < 1/2\}$, and let f_j be the function as in Corollary A.2, equal to 1 on B'_j and vanishing on $\mathfrak{X} \setminus B_j$. Finally, choose $\varepsilon_j > 0$ so that for $l = 0, 1, \ldots, L$,

$$\sum_{i=1}^{\infty} \varepsilon_i \left\| \Delta^l f_i \right\|_{L^\infty(\mathfrak{X})} < \frac{1}{2} \left\| \Delta^l f_0 \right\|_{L^\infty(\mathfrak{X})} .$$

Then $f = f_0 + \sum_{i=1}^{\infty} \varepsilon_i f_i$ has all the desired properties, with ε replaced by 2ε. □

Corollary A.4. *Assumption B holds with α-stable scaling.*

Proof. Given any compact subset K of an open set $D \subseteq \mathfrak{X}$, choose $\varepsilon > 0$ such that $\operatorname{dist}(\mathfrak{X} \setminus D, K) \geq \varepsilon$. Since $\mathcal{D}(\Delta) \subseteq \mathcal{D}(\mathcal{A})$, the function f given in Proposition A.3 (for $L = 1$) satisfies all conditions of Assumption B. Furthermore, if $\nu_\eta(s)ds$ is the Lévy measure of the subordinator η_t, then

$$\begin{aligned} \|\mathcal{A} f\|_{L^\infty(\mathfrak{X})} &= \left\| \int_0^\infty (T_s^Z f - f) \nu_\eta(s) ds \right\|_{L^\infty(\mathfrak{X})} \leq \int_0^\infty \left\| T_s^Z f - f \right\|_{L^\infty(\mathfrak{X})} \nu_\eta(s) ds \\ &\leq \int_0^\infty \min\left(s \left\| \Delta f \right\|_{L^\infty(\mathfrak{X})}, 2 \left\| f \right\|_{L^\infty(\mathfrak{X})} \right) \nu_\eta(s) ds. \end{aligned}$$

Note that $\|f\|_{L^\infty(\mathfrak{X})} = 1$. Furthermore, $\min(\lambda s, 2) \leq c_1(1 - e^{-\lambda s})$ (with $c_1 = 2e^2/(e^2 - 1)$), and

$$\int_0^\infty (1 - e^{-\lambda s}) \nu_\eta(s) ds = \lambda^{\alpha/d_w}.$$

Therefore,

$$\|\mathcal{A} f\|_{L^\infty(\mathfrak{X})} \leq c_1 \left(\|\Delta f\|_{L^\infty(\mathfrak{X})} \right)^{\alpha/d_w} .$$

Let $0 < r < R$, and take $K = \overline{B}(x_0, r)$, $D = B(x_0, R)$, $\varepsilon = R - r$. We see that

$$\|\mathcal{A} f\|_{L^\infty(\mathfrak{X})} \leq c_1 \left(\frac{c_{(A.5)}(1, Z_t)(2R)^{n/2}}{(R - r)^{d_w + n/2}} \right)^{\alpha/d_w} = c_2(r/R, Z_t) R^{-\alpha}.$$

This gives half of the α-stable scaling property (f), and the other half is proved in a similar manner. □

Acknowledgments. We express our gratitude to Moritz Kaßmann for many discussions on the subject of supremum bounds for sub-harmonic functions. We thank Tomasz Grzywny for pointing out errors in the preliminary version of the article. We also thank Luke Rogers for providing us with a new proof of Theorem 2.2 in [69].
